

Status report for the PANDA Cluster-Jet Target and the Prototype at Münster

Philipp Brand

WWU Münster, Institut für Kernphysik, Germany

PANDA collaboration meeting, June 22-26, 2020

Corona consequences in Münster

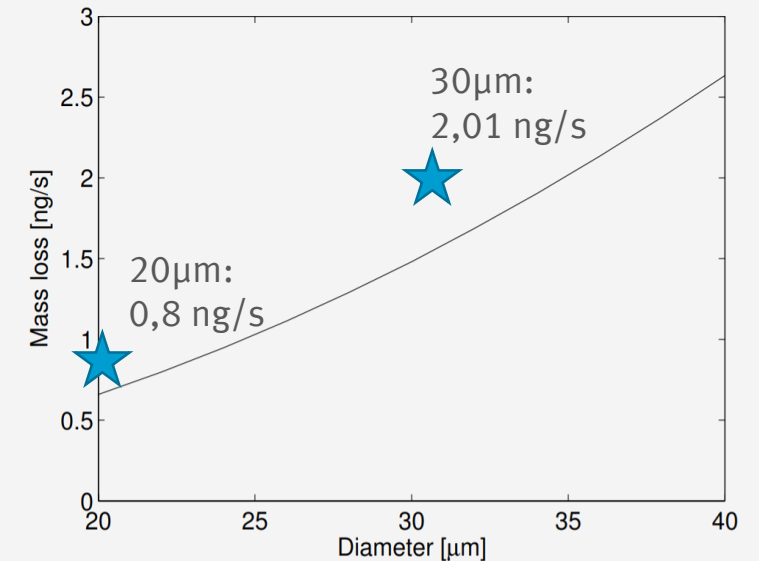

- Labs and institute were accessible the whole time, but limited manpower at the beginning
- Strict travel restrictions for more than two months, currently only absolutely necessary trips allowed
 - Planned beam time at COSY in Jülich was postponed
- No work at the PANDA cluster-jet target in Jülich possible for the last three months, we will resume the work there soon. This includes:
 - Installation of new chamber between source and IP to study origin of residual gas at IP
 - Preparation for the next beam time

Influence of clusters/pellets on the vacuum

- Vacuum inside the PANDA beamline not only induced by dump backflow.
- Microspheres (clusters and pellets) start as liquid droplets injected into vacuum.
 - Freezing and evaporation processes happening.
 - Finally reaching an equilibrium state with a solid microsphere core.
- Calculations recently started in Münster based on former calculations of Örjan Nordhage (Uppsala) for the WASA pellet target.
 - Key aspect will be the understanding of microspheres in the cluster-size regime.

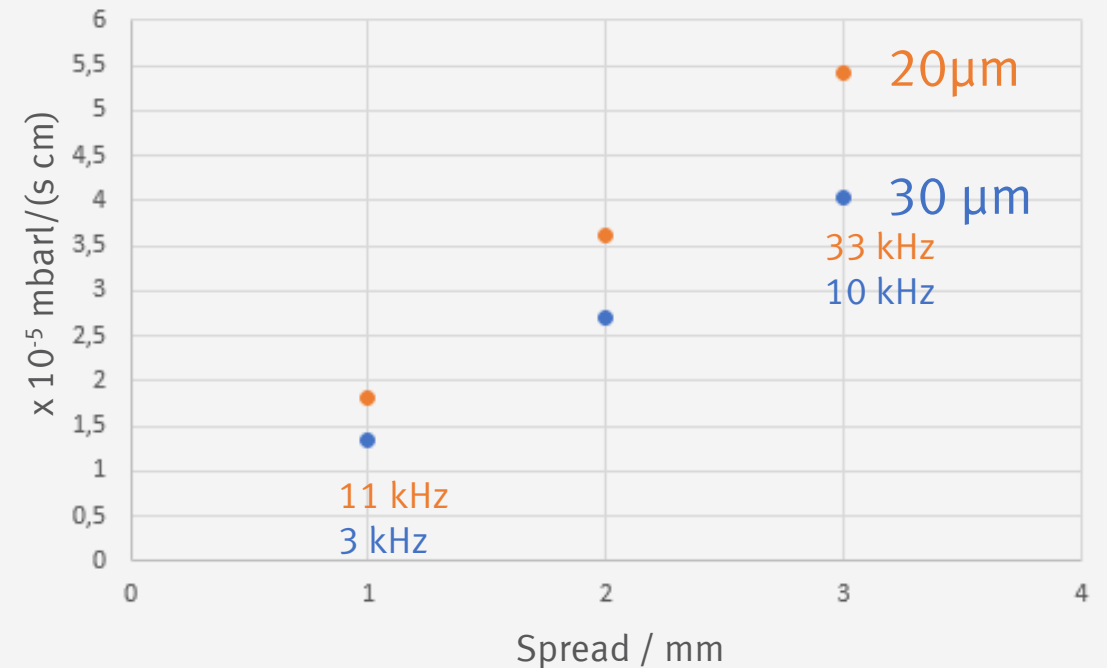

Influence of clusters/pellets on the vacuum

- Reproduction of ÖN's results successful using FEM simulations for two given microsphere sizes so far
- **Preliminary** results yield an effective gas load at IP using 30 μm pellets of
 - $\approx 2 \times 10^{-3}$ mbar l/s (ÖN) to (using a simple PANDA Model 2006)
 - $\approx 4 \times 10^{-3}$ mbar l/s (BH). (numbers calculated by using a realistic PANDA model in Molflow)

Influence of clusters/pellets on the vacuum

- Gas load induced by microspheres is depending on:
 - microsphere size and spread.
- Going down to cluster-size regime in next step.
- Things to consider in next steps:
 - Cluster size distribution inside jet beam,
 - jet beam size/spread different than pellet spread,
 - etc.

A new rod system for the prototype target

- New rod system at the scattering chamber of the prototype target
 - Exact copy of the system used at the final PANDA target at COSY
- Similar system is planned to use in a modified beam dump for the final PANDA setup

Cluster-Jet

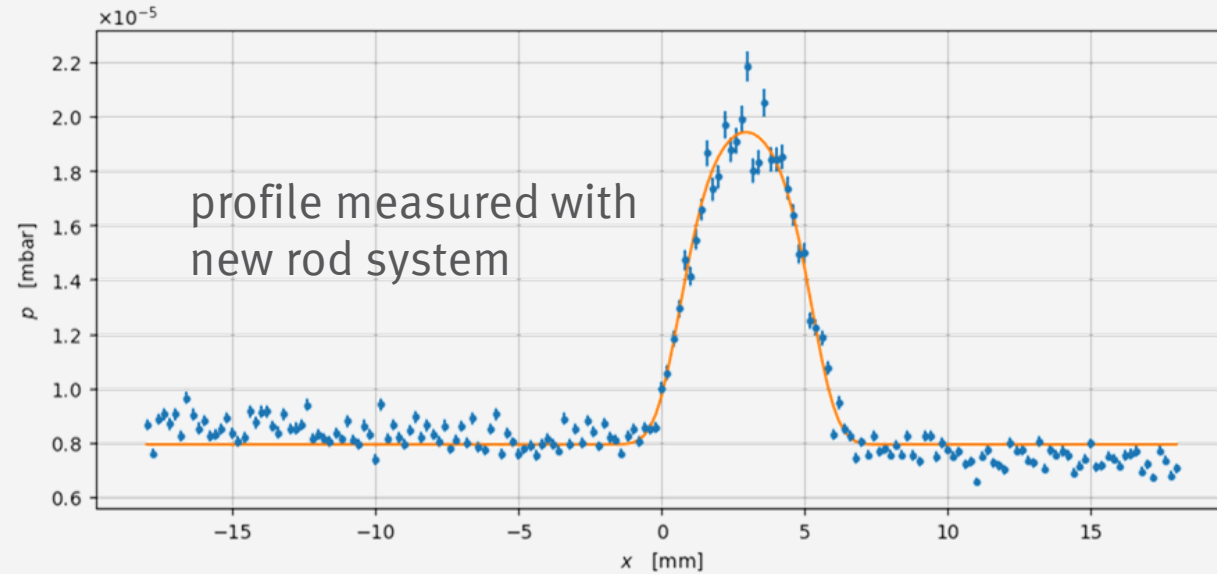

New glass nozzles

- Former glass nozzles had a maximum length of 3mm due to the production process
 - Standard copper nozzles have a length of 18mm
- Now nozzles up to 10mm can be produced by 3D laser etching (LightFab)

New glass nozzles

- First studies show a cluster-jet at least in the supercritical regime, more studies will follow
- Measurements in liquid regime are currently unstable, probably caused by the gas system

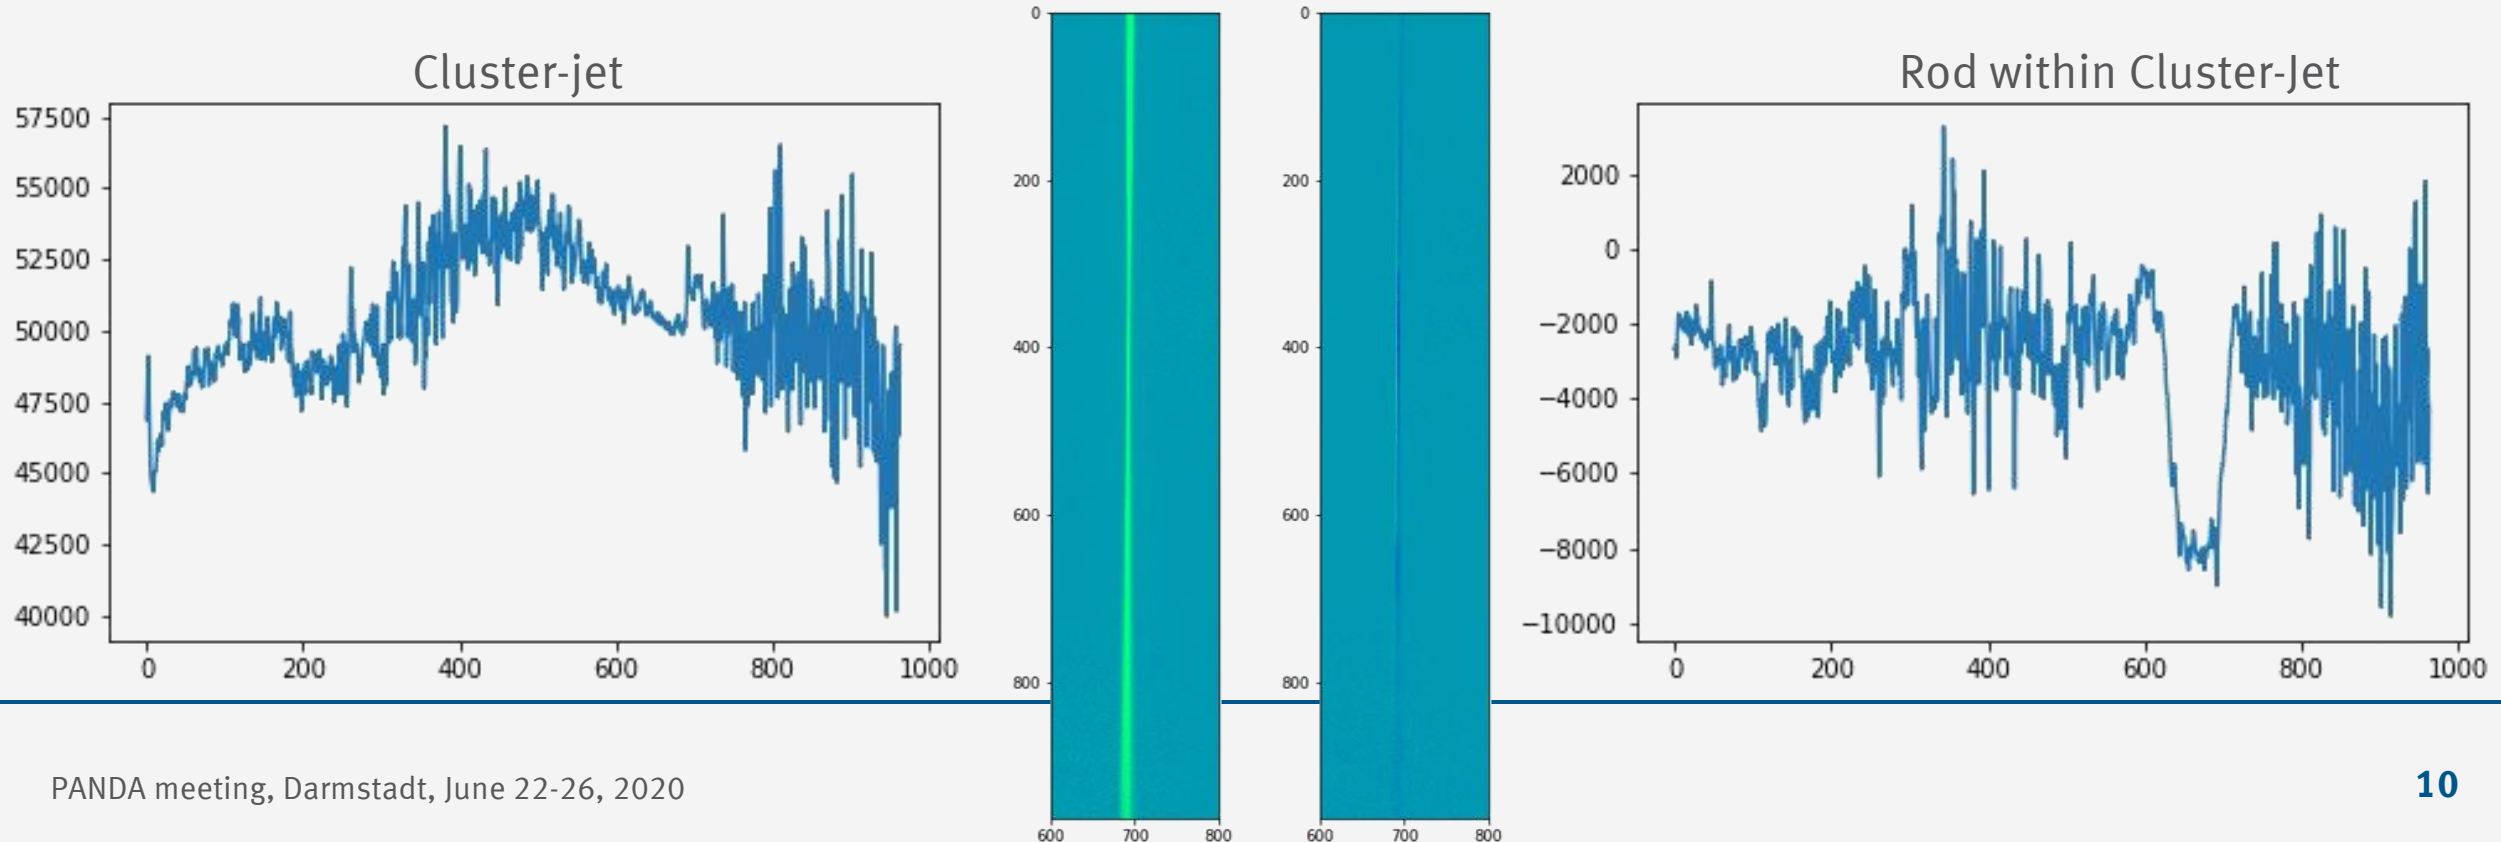

Exchange of the Hydrogen Purifier

- New hydrogen purifier for the prototype target was delivered
- Same model is used for final PANDA target, we can gather experience for routine PANDA operation
- Will be installed soon with a completely renewed gas system, instabilities will be solved

Laser system within the beam dump of the prototype

- Cluster-jet is illuminated by point laser, scattered light detected by CCD camera

Laser system within the beam dump of the prototype

- Cluster-jet is illuminated by point laser, scattered light detected by CCD camera
- First simple setup shows huge background due to
 - The very simple laser dump
 - Dead end of prototype beam dump without pumping power
- Nevertheless a rod within the cluster-jet can be identified
- Upgrade will have a line laser to visualize a 2D cross section of the jet

Further ongoing work

- Data analysis of latest beam times
- Design of a modified beam dump, including new monitor systems
- Influence of the nozzle length on cluster production by shortening a copper nozzle
- Design and first tests of a cryopump (following talk by C. Mannweiler)

Thank you for your attention!
