16.06.2021

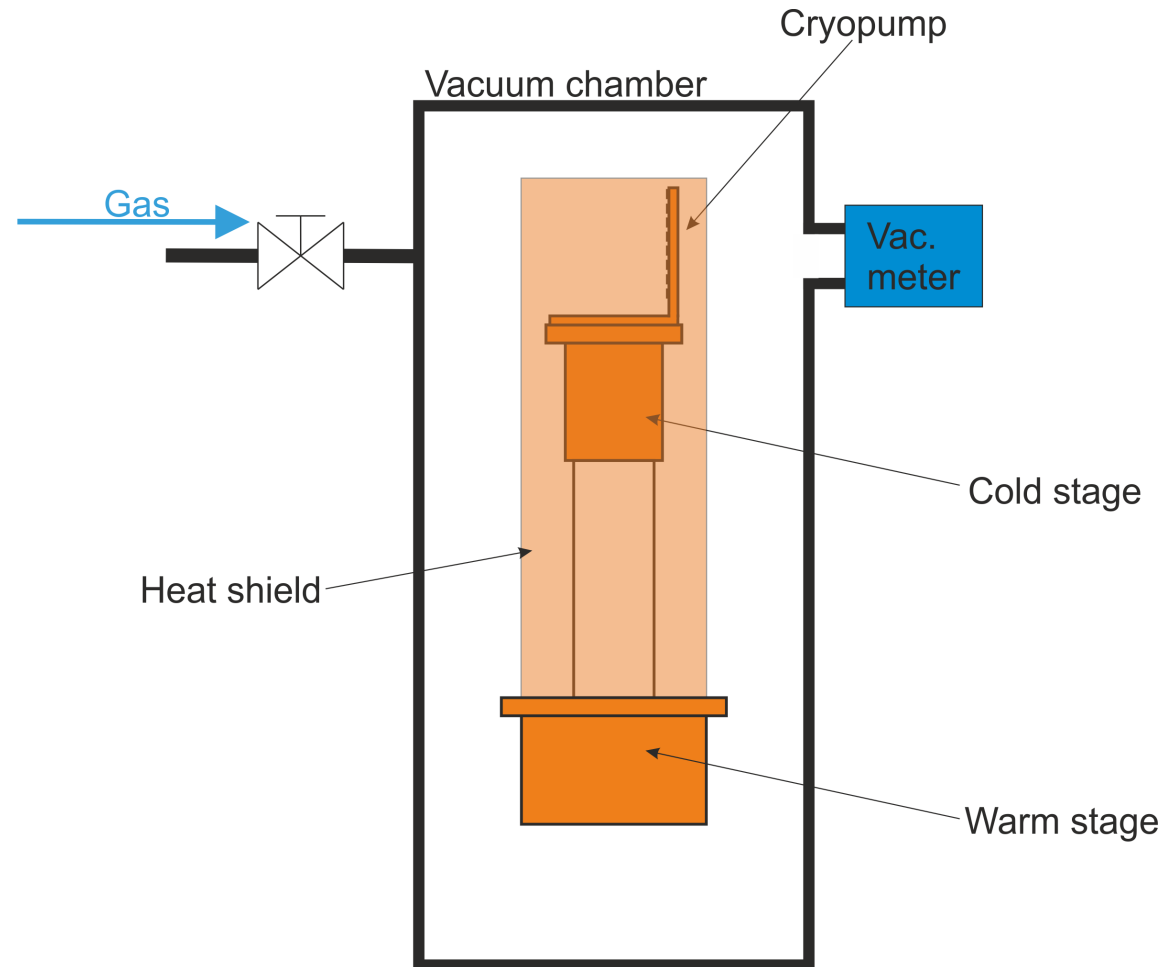

Review of last time

- Design for the beam pipe section containing the cryopump.
- Simulations of the effects of uneven distribution of rest gas on the regeneration interval.
- Temperature simulations concerning the effects of glue and activated charcoal

- **Today: First experimental results!**

Experimental Setup:

Experimental setup:

Temperature diodes

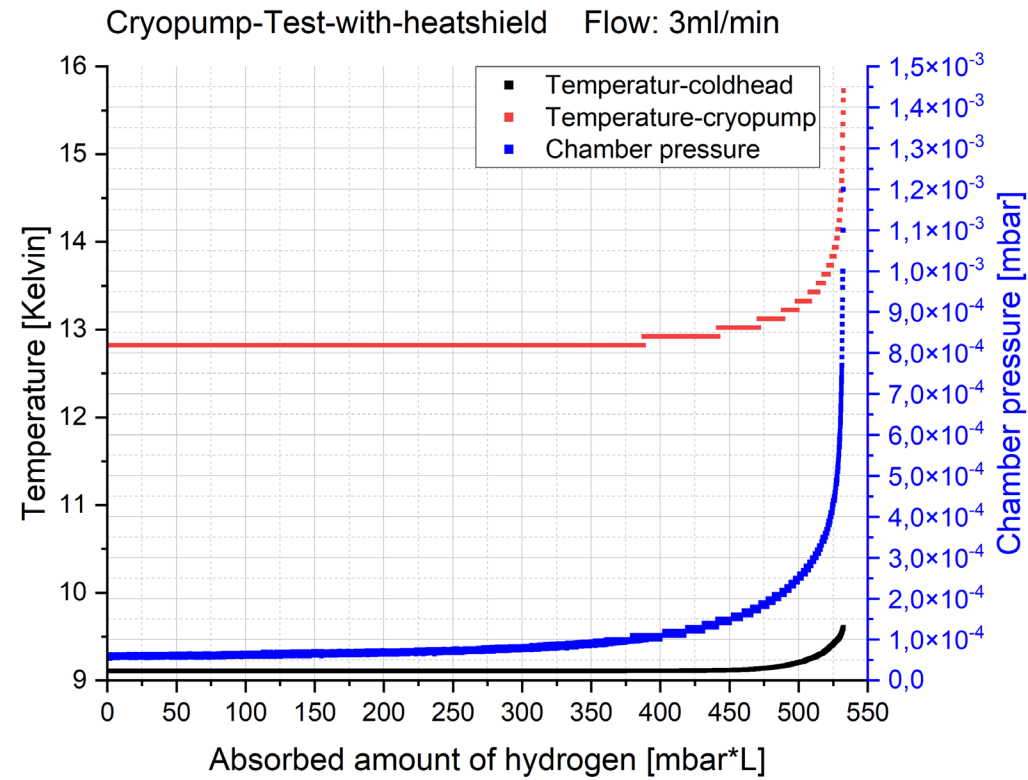

- Dimensions: 40mm x 87.5mm
- Pumping area: 35 cm²

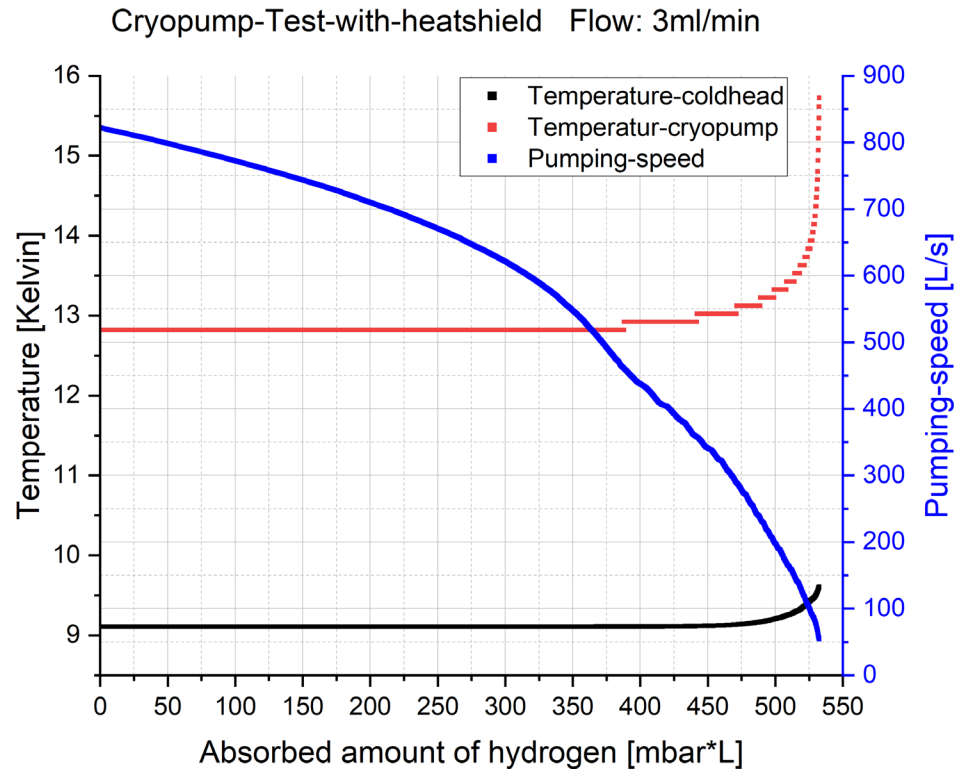

Experimental Setup:

Experimental results

Experimental results

- This particular cryopump has a pumping speed of $\approx 800\text{l/s}$ and a capacity of $\approx 413\text{mbar}\cdot\text{L}$
- Extrapolating to a full size cryopump for PANDA:
 - Pumping speed of $\approx 100,000\text{l/s}$
 - Regeneration interval of ≈ 2 months (assuming outgassing rate of $0.01\text{ mbar}\cdot\text{l/s}$)

Next steps:

- A prototype cryopump is being designed
- Modular design
- Testbed for features such as gentle degas mode

Next steps:

- A prototype cryopump is being designed
- Modular design
- Testbed for features such as gentle degas mode

Summary

- A small test cryopump was built and tested:
 - PANDA cryopump has a pumping speed of $\approx 100,000\text{l/s}$ and a regeneration interval of 2 months
- A prototype is being designed which will form the basis for the final cryopump

Thank you for your attention
