## Structure and Energy of Isomeric States of some Well-Deformed Even-Even Rare-Earth and Actinide Nuclei, a Microscopic Approach

Monday, 2 May 2022 12:00 (15 minutes)

The single particle (sp) structure of isomeric states of some well-deformed even-even nuclei in the rare-earth and actinide regions is studied within a self-consistent Hartree-Fock plus BCS approach (with blocking)[1]. The well studied Skyrme SIII parametrisation is used for the particle-hole part of the nuclear interaction and a seniority force for its residual part. The parameters of the latter have been carefully adjusted to reproduce the moments of inertia of the first 2+ states separately in each region. The criterion to assess the relevance of our results is the fair reproduction of the isomeric energy as obtained from two independent self-consistent calculations [1,2]. The calculations will be limited to merely seniority-two states for each charge states (possibly combining them). A particular effort will be devoted to study the well-documented isomeric states around the 178Hf nucleus. The polarisation effects due to the sp excitations from what is obtained in the ground states for time-even moments of the density will be discussed.
