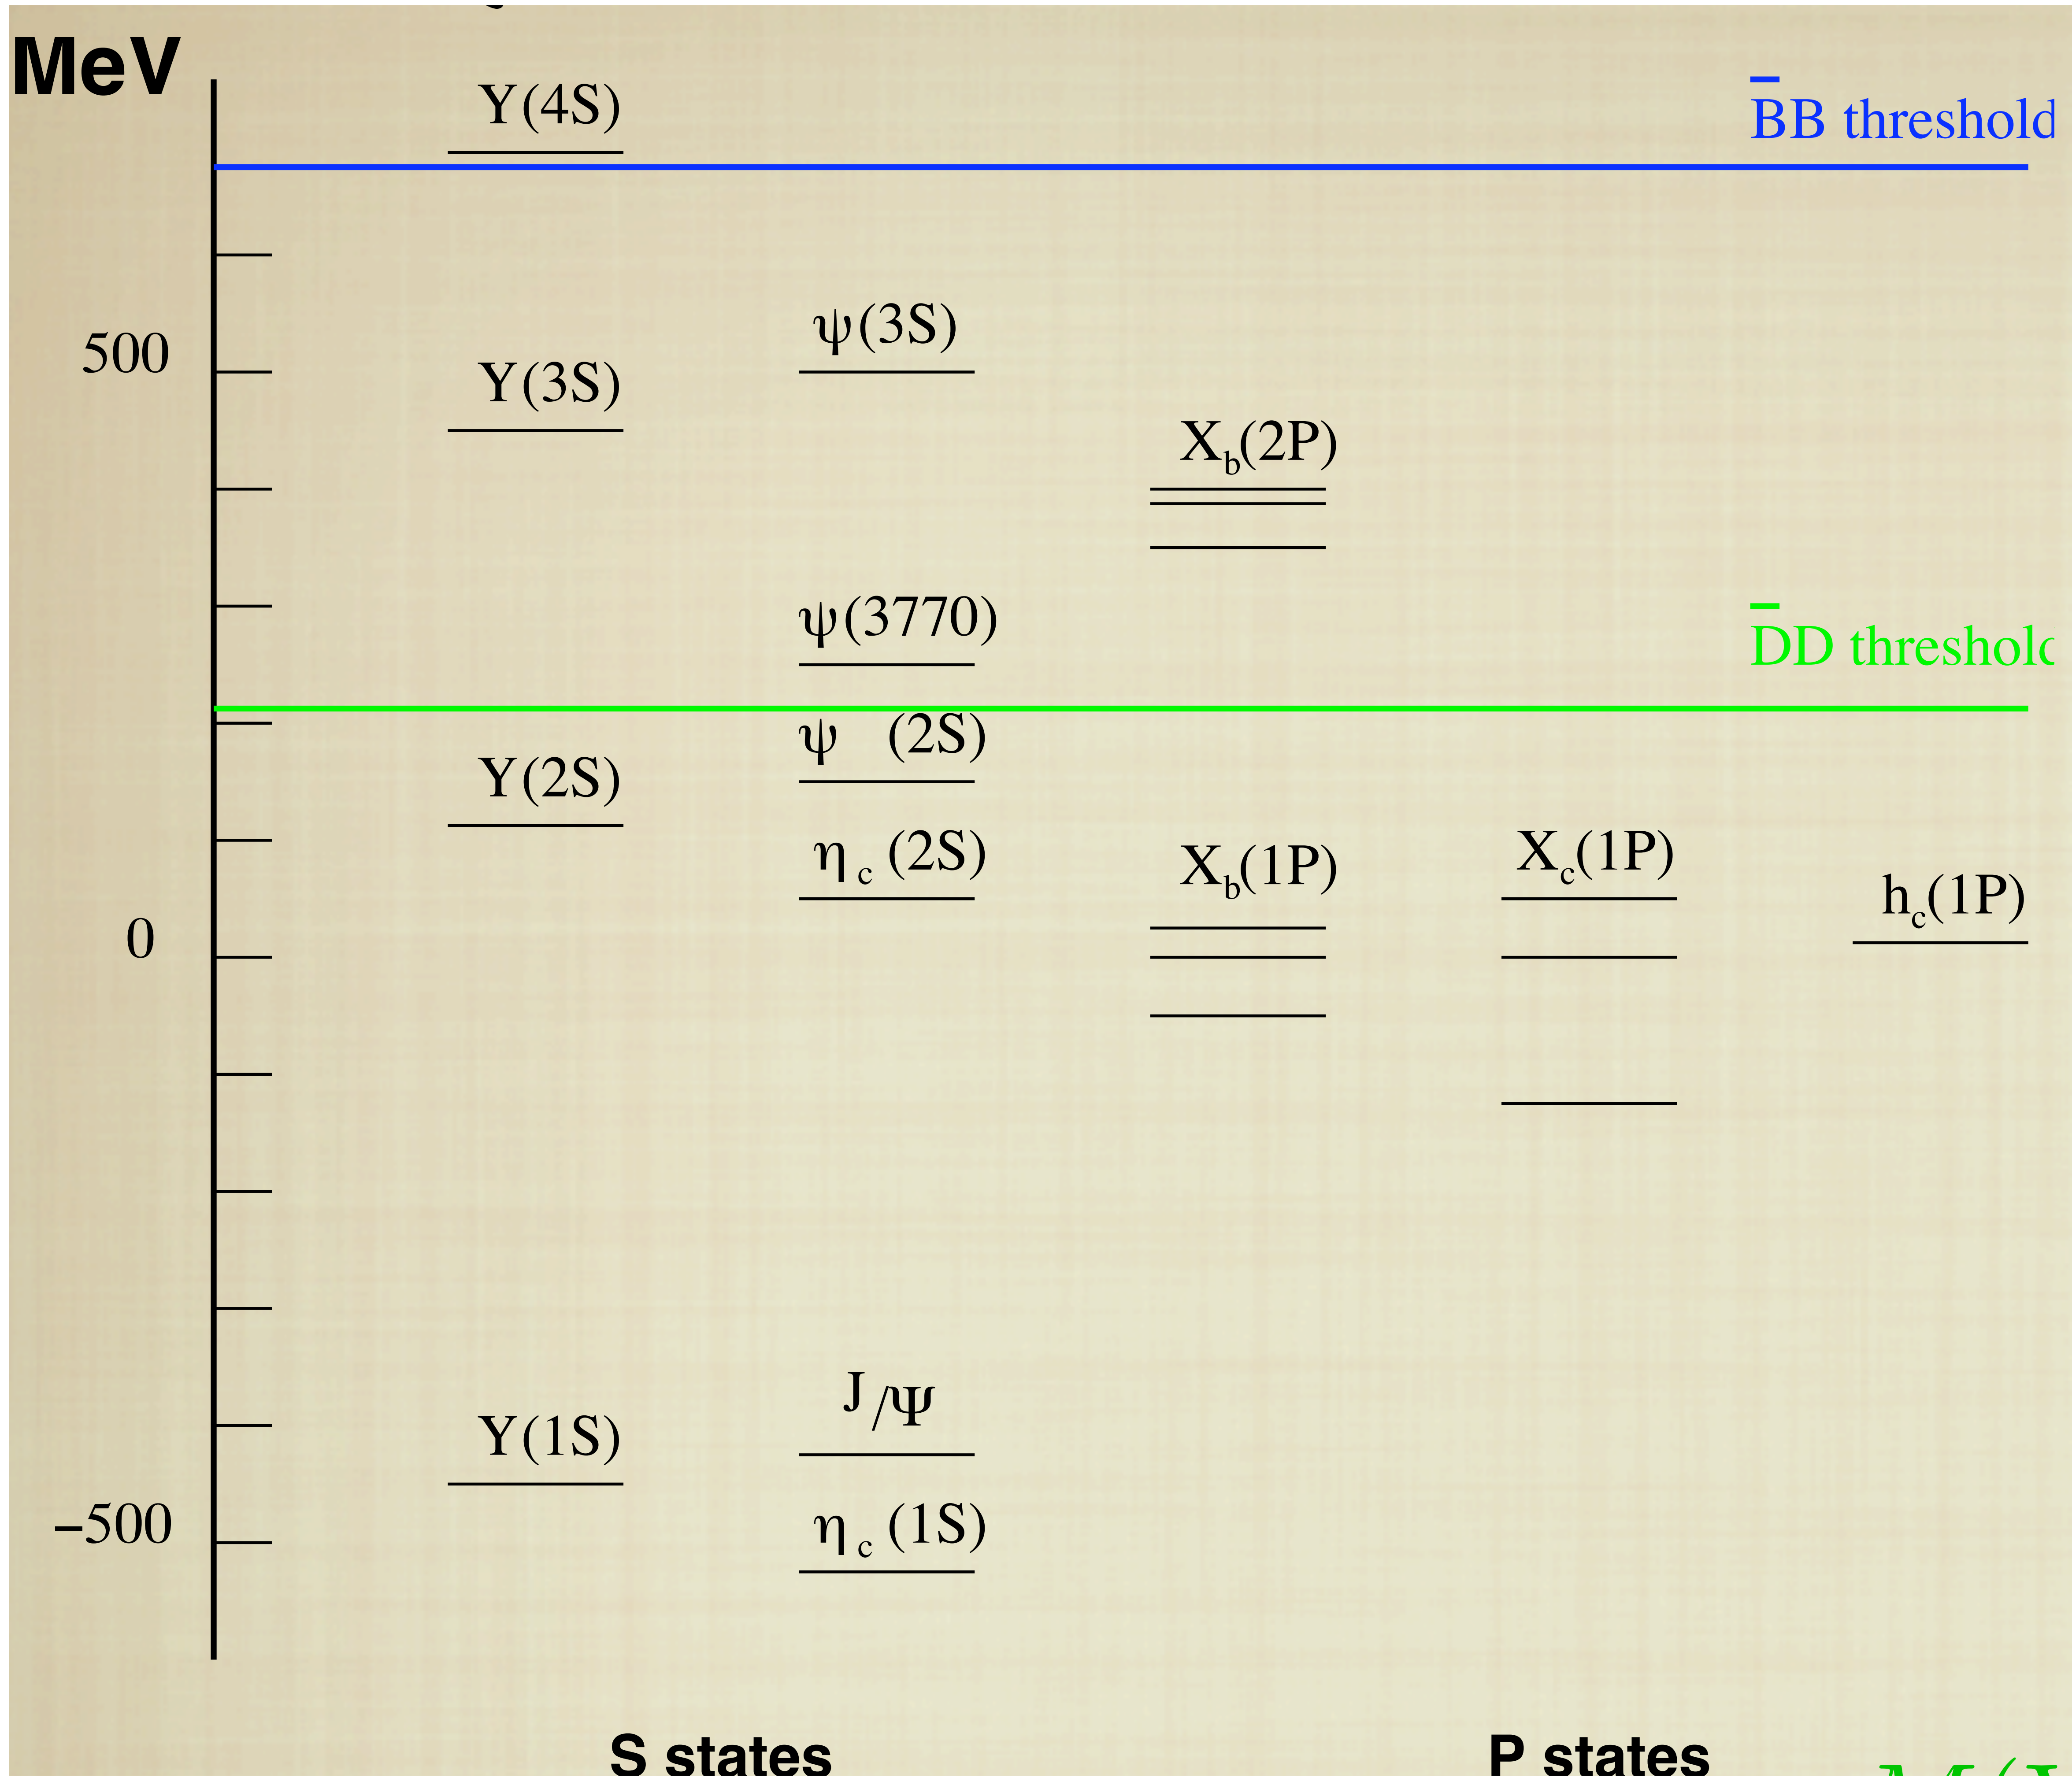
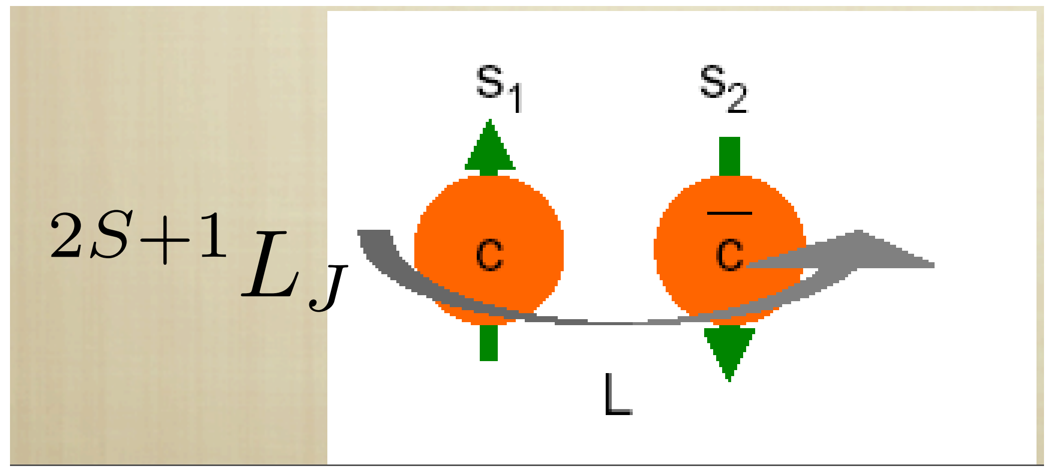
Heavy quarkonia are nonrelativistic systems:multiscale systems

Many scales: a challenge and an opportunity

Quarkonium scales



Levels normalized with respect to $\chi_b(1P)$ and $\chi_c(1P)$



$M(\Upsilon(1S)) = 9460\,\mathrm{GeV}$

$M(J/\Psi) = 3097\,\mathrm{GeV}$

The mass scale is perturbative

$$m_Q \gg \Lambda_{\mathrm{QCD}}$$

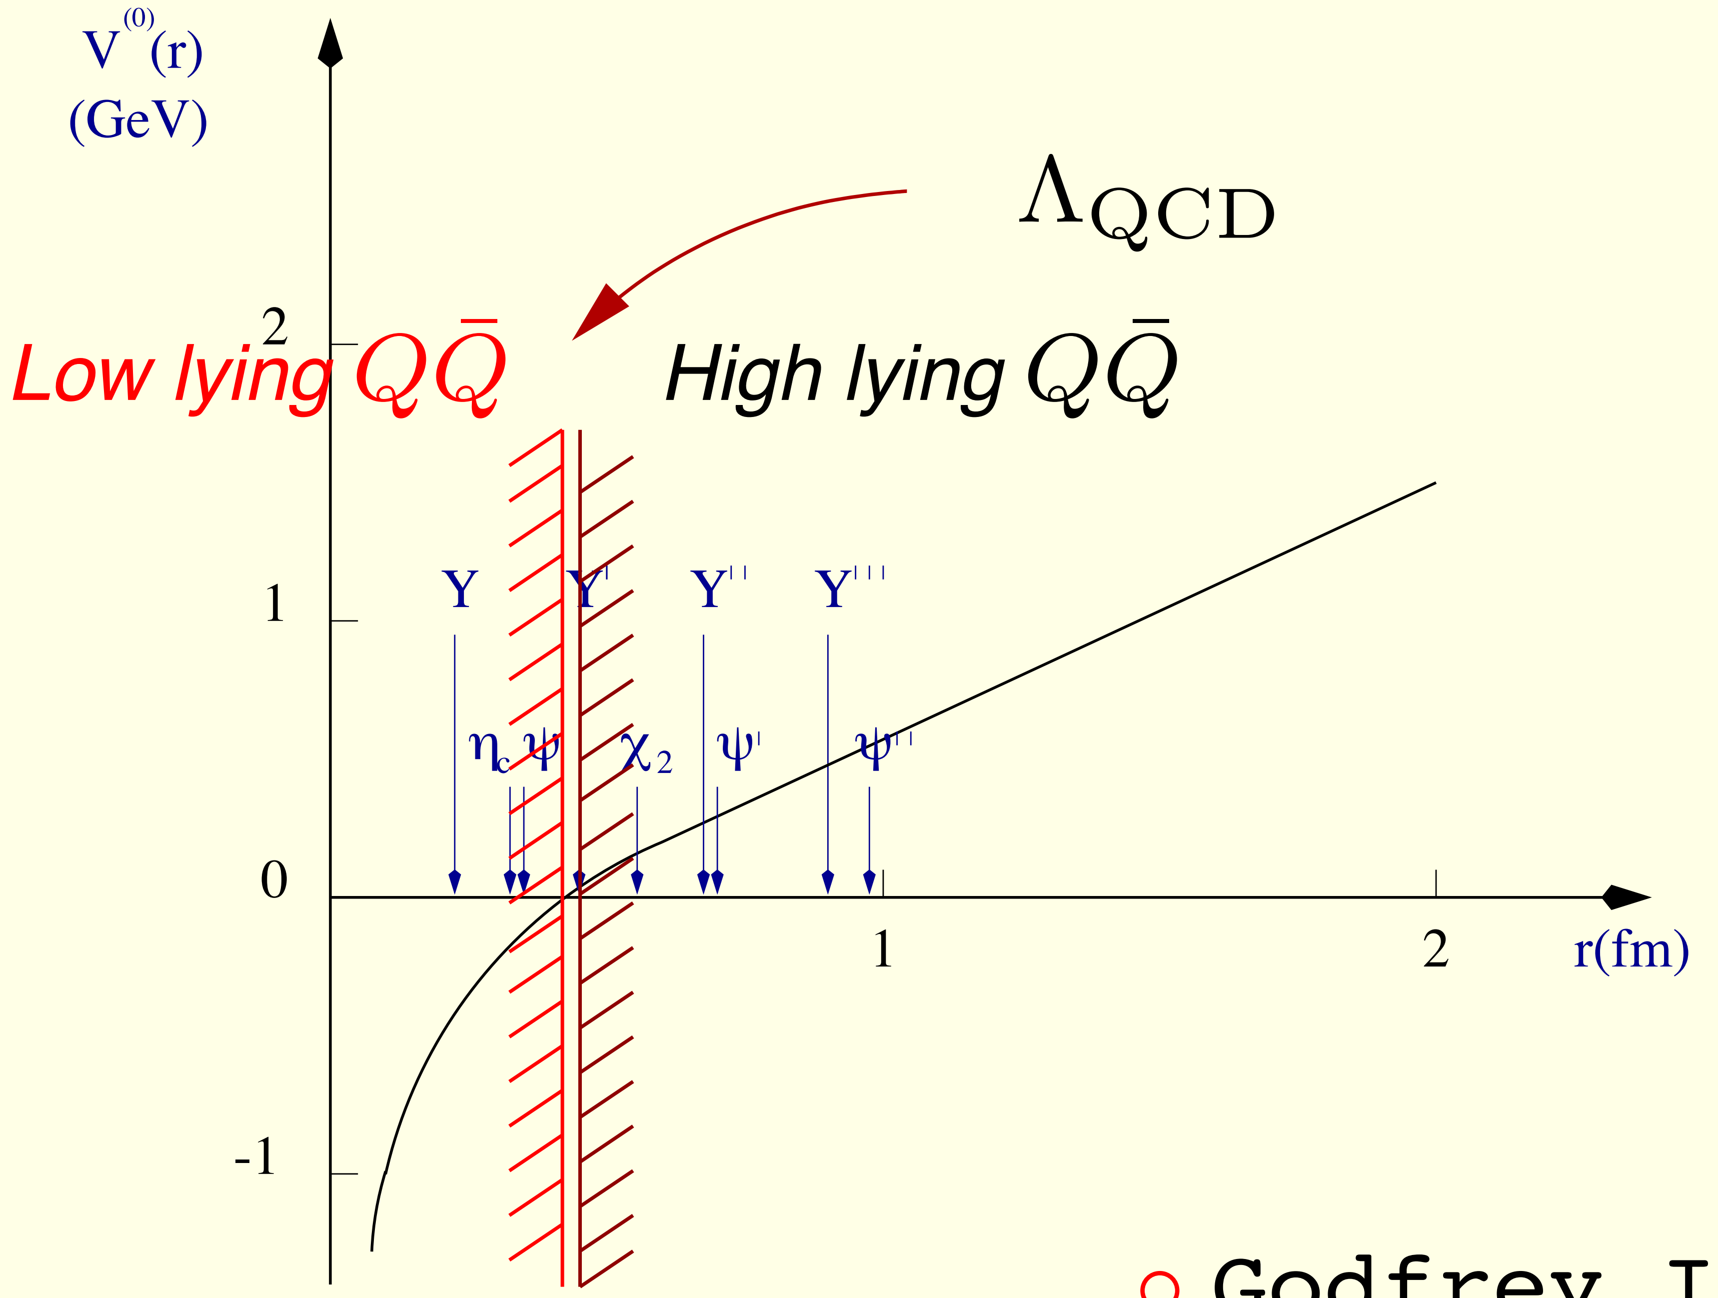
The rich structure of separated energy scales makes QQbar systems an ideal probe of strong interactions

- The different quarkonium radii provide different measures of the transition from a Coulombic to a confined bound state.



- Godfrey Isgur PRD 32(85)189

quarkonia probe the perturbative (high energy) and non perturbative region (low energy) as well as the transition region in dependence of their radius r

XYZs not merely composite particles, have unique properties

Novel strongly correlated exotics systems

It is of fundamental interest to provide first principle predictions for spectra, transitions, production and medium evolution from QCD

We need a flexible approach rooted in QCD that can address all properties of XYZ spectra, production and propagation in medium : Born Oppenheimer Effective Field Theory (BOEFT)

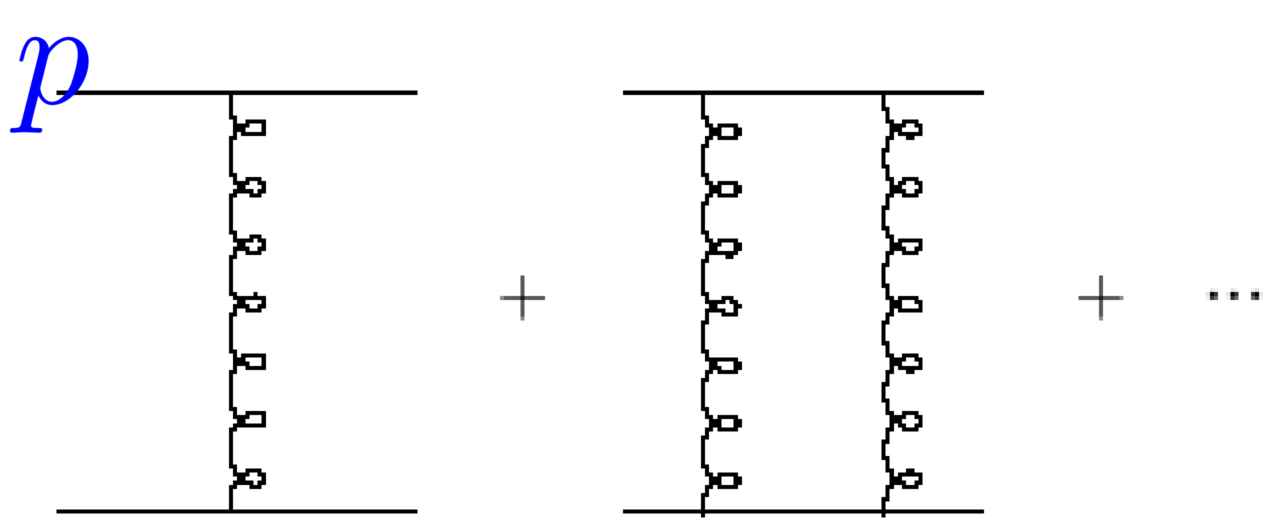
For quarkonium to become a probe of strong interactions, it should be treated in QCD :a very hard problem

Close to the bound state $\alpha_s \sim v$

Q

$p \sim m\alpha_s$

$\bar{Q}$



$$\frac{g^2}{p^2}\left(1+\frac{m\alpha_s}{p}\right)$$

$$\sim \frac{1}{E-\left(\frac{p^2}{m}+V\right)}$$

- From $(\frac{p^2}{m}+V)\phi = E\phi \to p \sim mv$ and $E = \frac{p^2}{m} + V \sim mv^2$.

pNRQCD and the potentials come from integrating out all scales up to mv^2

- gluonic excitations develop a gap $\Lambda_{\rm QCD}$ and are integrated out

- A pure potential description emerges from the EFT **however this is not the constituent quark model, alphas and masses are the QCD fundamental parameters**

- The potentials $V = {\rm Re}V + ImV$ from QCD in the matching: get spectra and decays

- We obtain the form of the nonperturbative potentials V in terms of generalized Wilson loops (stat that are low energy pure gluonic correlators: all the flavour dependence is pulled out

- the flavour dependent part is extracted in the NRQCD matching coefficients
- the nonperturbative part is universal:factorized and depends only on the glue —> only one lattice calculation to get the dynamics and the observables instead of an ab initio calculation of multiple Green functions

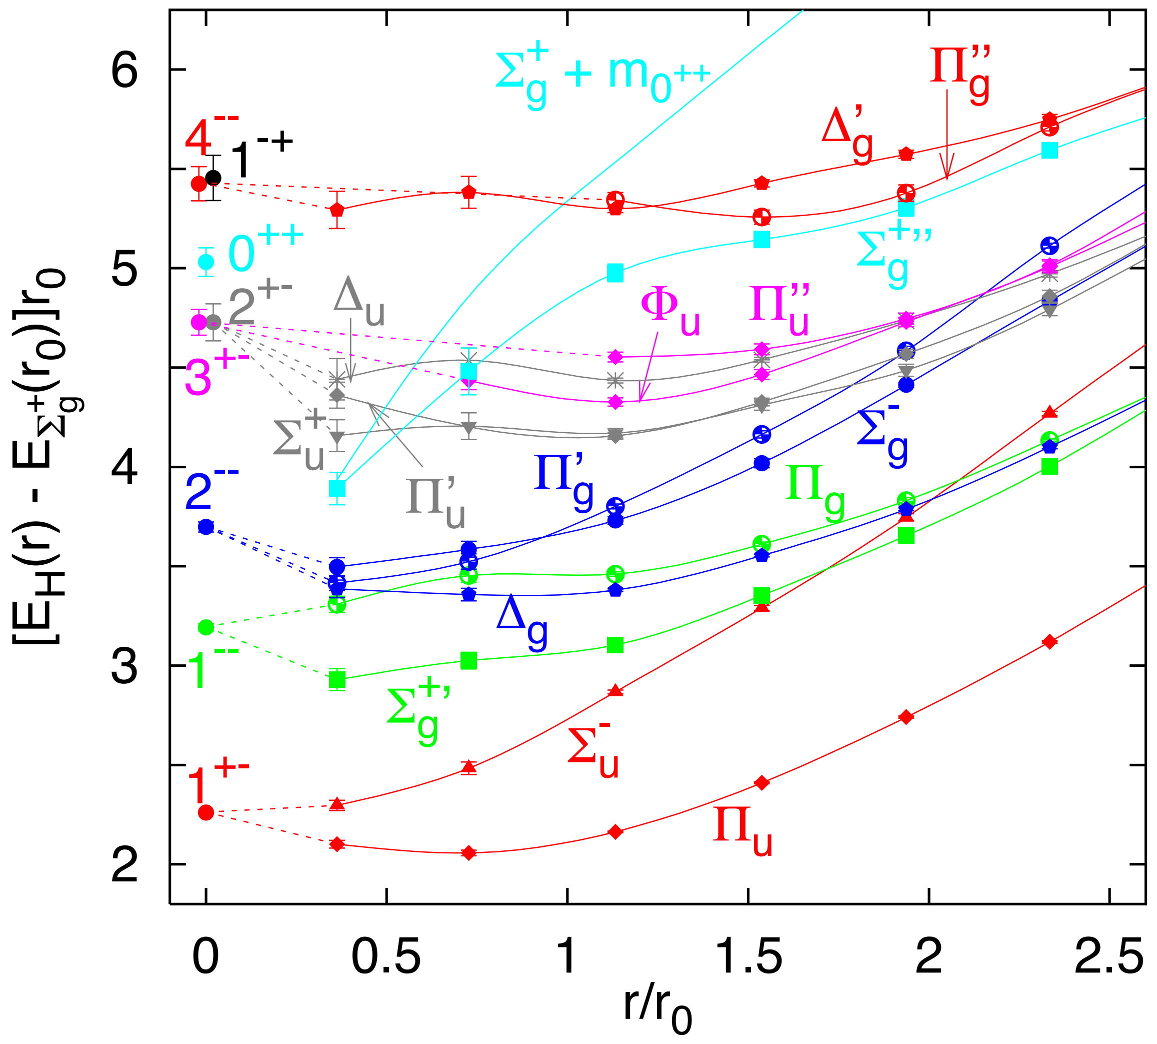
BOEFT for HYBRIDS

Hybrids static energies at short distances

We can calculate the perturbative behaviour of the potential for short distance



In the short-range hybrids become gluelumps, i.e., quark-antiquark octets, O^a, in the presence of a gluonic field, H^a: $H(R,r,t) = H^a(R,t)O^a(R,r,t)$.

the hybrid static energy can be written as a (multipole) expansion in r:

octet potential

non perturbative coefficient

$$E_g = \frac{\alpha_s}{6r} + \Lambda_g + a_g r^2 + \ldots$$

Λ_g is the gluelump mass: $\Lambda_g = \lim_{T\to\infty} \frac{i}{T} \ln\langle H^a(T/2)\phi^{\rm adj}_{ab}(T/2,-T/2)H^b(-T/2)\rangle$

Features:

- New spin structures with respect to the quarkonium case: all terms at order 1/m and two terms at order 1/m^2

Differently from the quarkonium case, the hybrid potential gets a first contribution already at order $\Lambda^2_{\mathrm{QCD}}/m_h$. The corresponding operator does not contribute at LO to matrix elements of quarkonium states as its projection on quark-antiquark color singlet states vanishes. Hence, spin splittings are remarkably less suppressed in heavy quarkonium hybrids than in heavy quarkonia.

$\left(K^{ij}\right)^{k} = i\epsilon^{ikj}$ is the angular momentum of the spin one gluons

$\boldsymbol{L}$ is the orbital angular momentum of the heavy-quark-antiquark pair.

Features:

- The nonperturbative part in V_i (r) depend on nonperturbative gluonic correlators non local in time not yet calculated on the lattice: six unknowns, the octet perturbative part can be calculated in perturbation theory
- The only flavor dependence is carried by the perturbative NRQCD matching coefficients

the perturbative part produces a pattern opposite to the lattice and to ordinary quarkonia —> discrepancy can be reconciled thanks to the nonperturbative parts, especially the one at order 1/m which goes like Lambda^2/m and is parametrically larger than the perturbative contribution at order m v^4

which is interesting as some models are taking the spin interaction from perturbation theory with a constituent gluon

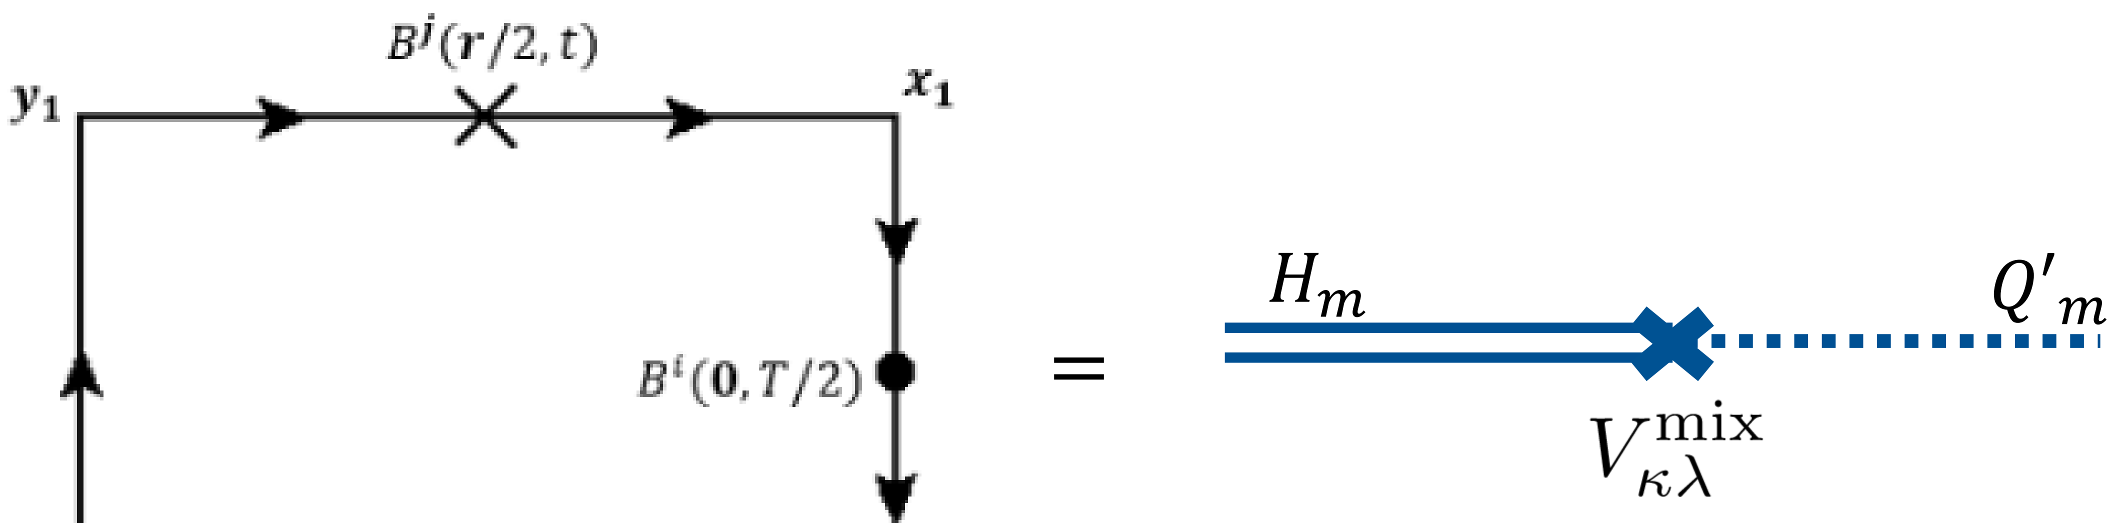
- Hybrid states in the same energy range and same quantum #'s as quarkonium can mix.

Ex. $H_1\,[1^{--}]\,(4155) \leftrightarrow c\bar{c}\,[1^{--}]\,(3S)$

Effect on decay: $H_m \leftrightarrow Q'_m \rightarrow (\eta_c, J/\psi, \cdots) + (\gamma, \cdots)$

- Mixing potential $V^{\rm mix}_{\kappa\lambda}$: determined from matching NRQCD and BOEFT at $O(1/m)$



NRQCD BOEFT

Expression after matching:

$$\boxed{V^{\rm mix}_{|\lambda|} = -\frac{g c_F}{2m_Q}\, {}^{(0)}_{\lambda}\langle 1|B^j\,(\mathbf{r}/2,0)\,|0\rangle^{(0)} P^j_\lambda,}$$

Above expression can be computed on lattice if we identify: $|0\rangle^{(0)} = |\Sigma_g^+\rangle$

$$|1\rangle^{(0)}_{\lambda=0} = |\Sigma_u^-\rangle, |1\rangle^{(0)}_{|\lambda|=1} = |\Pi_u\rangle$$

BOEFT may be used to describe any system made by two heavy quarks bound adiabatically with some light quarks degrees of freedom (tetraquarks QQlight quarks, QQbar light quarks, pentaquarks)

In case of light quarks isospin quantum numbers should be added

Steps go as before:

—identify the symmetries, identify the interpolating operators O_n

$$\mathcal{O}_n(t,\,\boldsymbol{r},\,\boldsymbol{R}) = \chi(t,\,\boldsymbol{R}-\boldsymbol{r}/2)\phi(t,\,\boldsymbol{R}-\boldsymbol{r}/2,\boldsymbol{R})H_n(t,\,\boldsymbol{R})\phi(t,\,\boldsymbol{R},\boldsymbol{R}+\boldsymbol{r}/2)\psi^\dagger(t,\,\boldsymbol{R}+\boldsymbol{r}/2)$$

—define the static energies

$$E_n^{(0)}(r) = \lim_{T\to\infty}\frac{i}{T}\log\langle\mathcal{O}_n(T,\,\boldsymbol{r},\,\boldsymbol{R})|\mathcal{O}_n(0,\,\boldsymbol{r},\,\boldsymbol{R})\rangle$$

-obtain the coupled Schroedinger equations in BOEFT

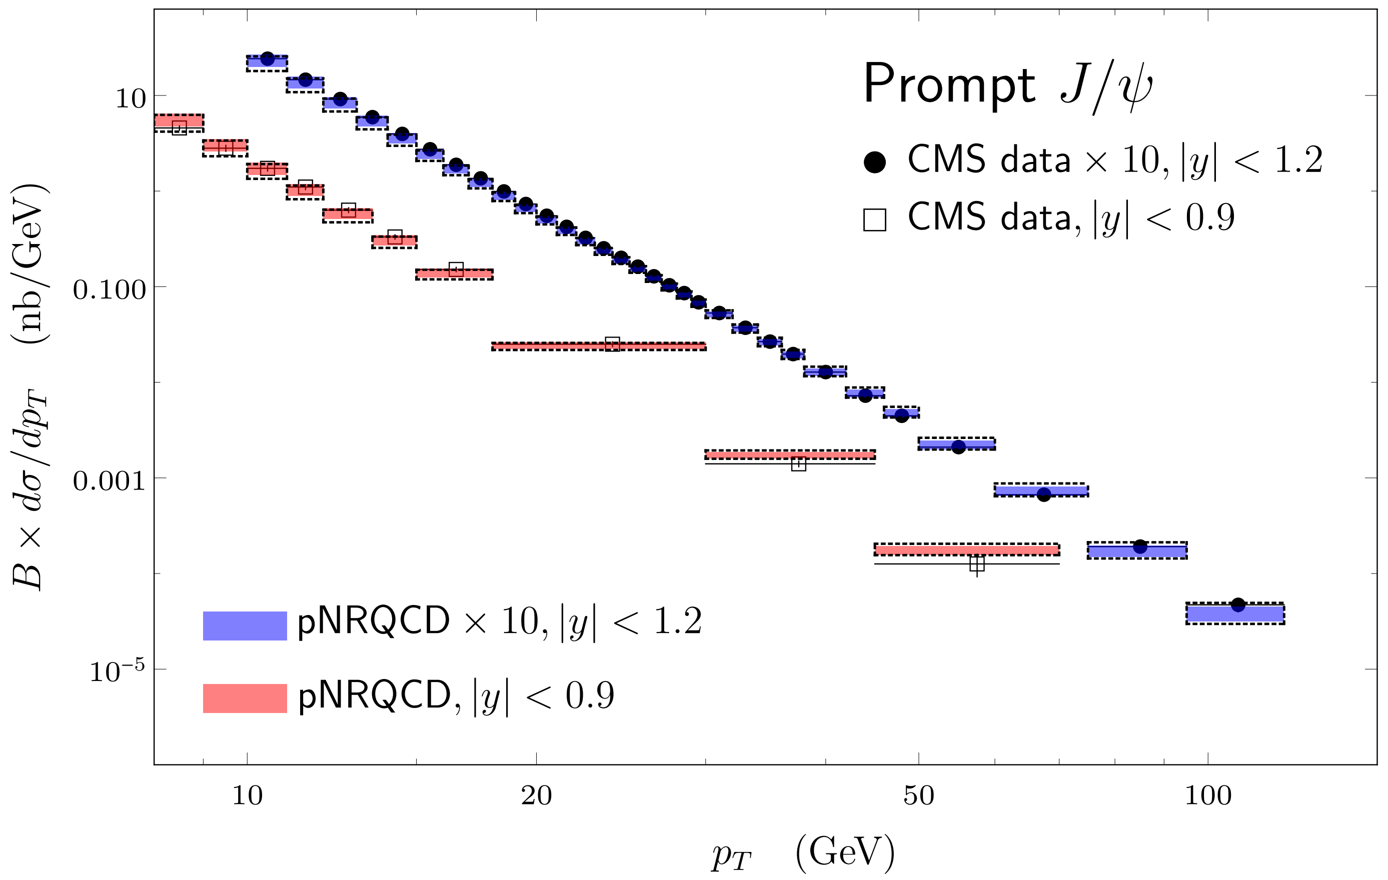
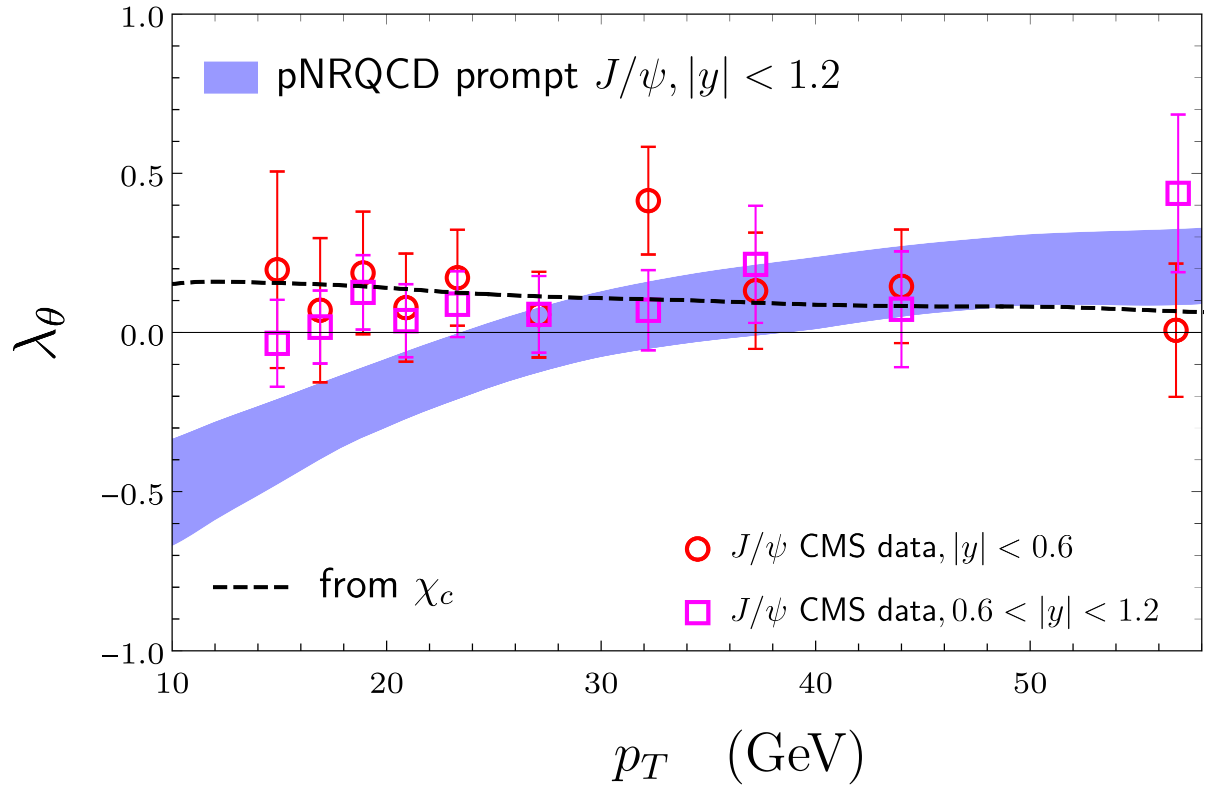
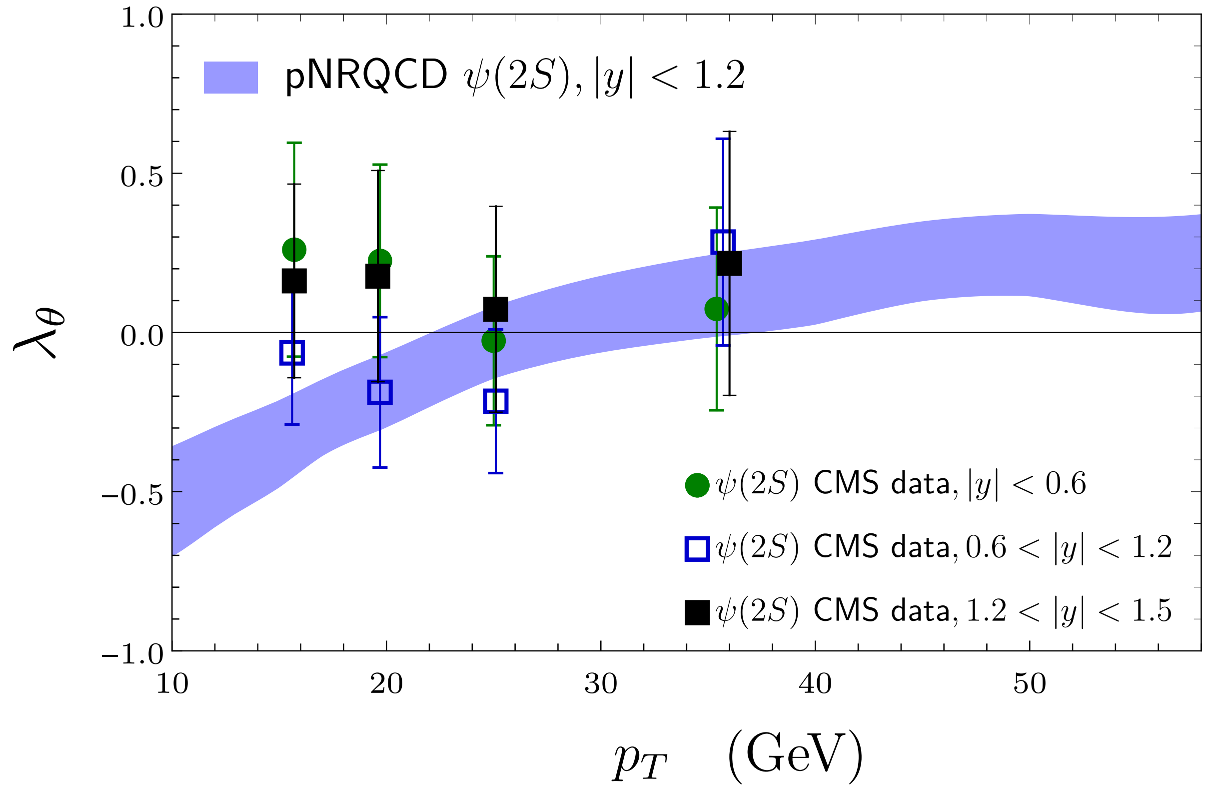
Quarkonium production can factorized and calculated in pNRQCD

N.B., Chung, Vairo, Wang 2210.17345







Outlook

NREFTs and lattice allows us to describe the physics of quarkonium away from the strong decay threshold in quantum field theory: higher order perturbative calculation can be performed and quarkonium can be used for precision physics/ factorisation allows to systematically studyconfinement

BOEFT allows to describe hybrids: new unexpected features are found (Lambda doubling, Spin structure, decays, mixing) that have important impact on the phenomenology

BOEFT allows to describe hybrids and calculate multiplets, mixing and decays: on going work

The same picture can be extended to tetraquarks and pentaquarks, once some lattice input on relevant correlators will be available.

NOTICE that the needed lattice calculations are simpler than the direct calculations of the X Y Z properties on the lattice, the knowledge of few correlators together with the BOEFTwill allow to obtain many phenomenological information

NREFTs and lattice and open quantum system allows us to describe the nonequilibrium evolution quarkonium in the quark gluon plasma and production processes: same theory could be then used for XYZ production and evolution in medium in heavy ion collisions

This picture has the possibility to give a unified description to exotics and to leave the dynamics decide which configuration will dominate in a given range

TABLE II. Predictions for tetraquark masses and binding energies for all combinations of tetraquarks involving only b and c quarks at each order of pNRQCD indicated. Pairs of tetraquarks in the same row have identical binding energies in our calculations due to charge conjugation.

Spectrum: with mixing and Λ-doubling

- The Schrödinger equation mixes states with the same parity. A consequence is Λ-doubling, i.e., the lifting of degeneracy between states with opposite parity. This happens also in molecular physics, however, there Λ-doubling is a subleading effect, while it is a LO effect in the quarkonium hybrid spectrum.
- The eigenstates are organized in the multiplets H_1, H_2, ... Neglecting off-diagonal terms, the multiplets H_1 and H_2 would be degenerate.
- We compute the spectrum using quark masses in the renormalon subtraction (RS) scheme: $m_{c\,\mathrm{RS}} = 1.477(40)$ GeV and $m_{b\,\mathrm{RS}} = 4.863(55)$ GeV.

  The gluelump masses, which enter in the normalization of the hybrid potentials, have been computed in the same scheme and assigned an uncertainty of ± 0.15 GeV, which is the largest source of uncertainty in the hybrid masses.
