

# **Preliminary results from FOOT test in Jülich**

Valerii Panin and William Stafford, University of Bristol  
(GSI summer student program)

FOOT inside black box

Experimental setup in Jülich

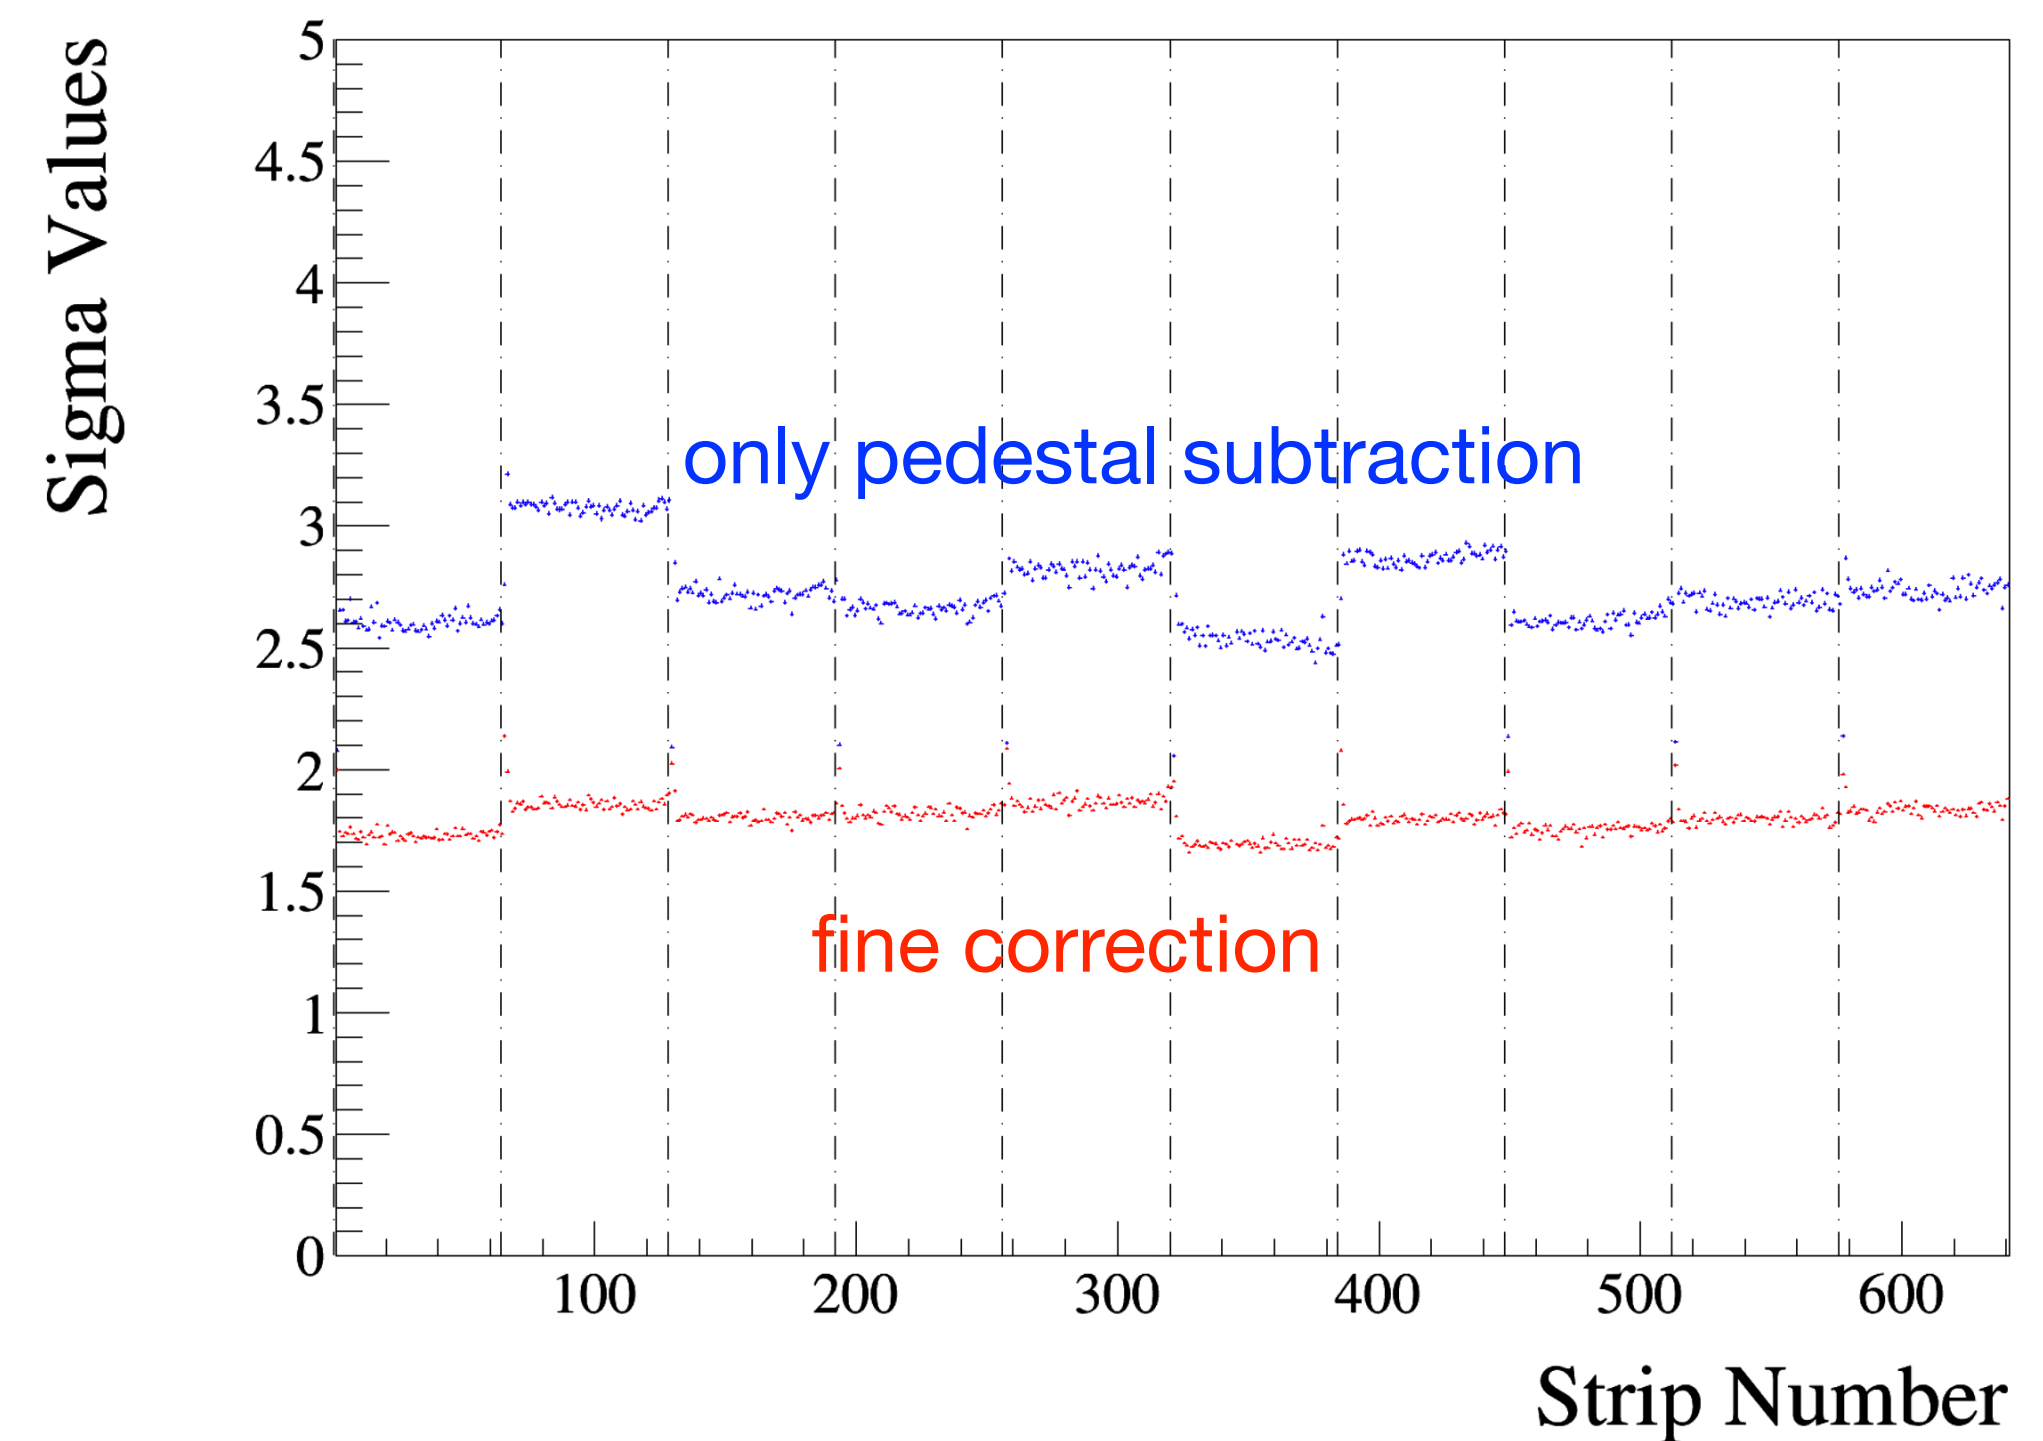

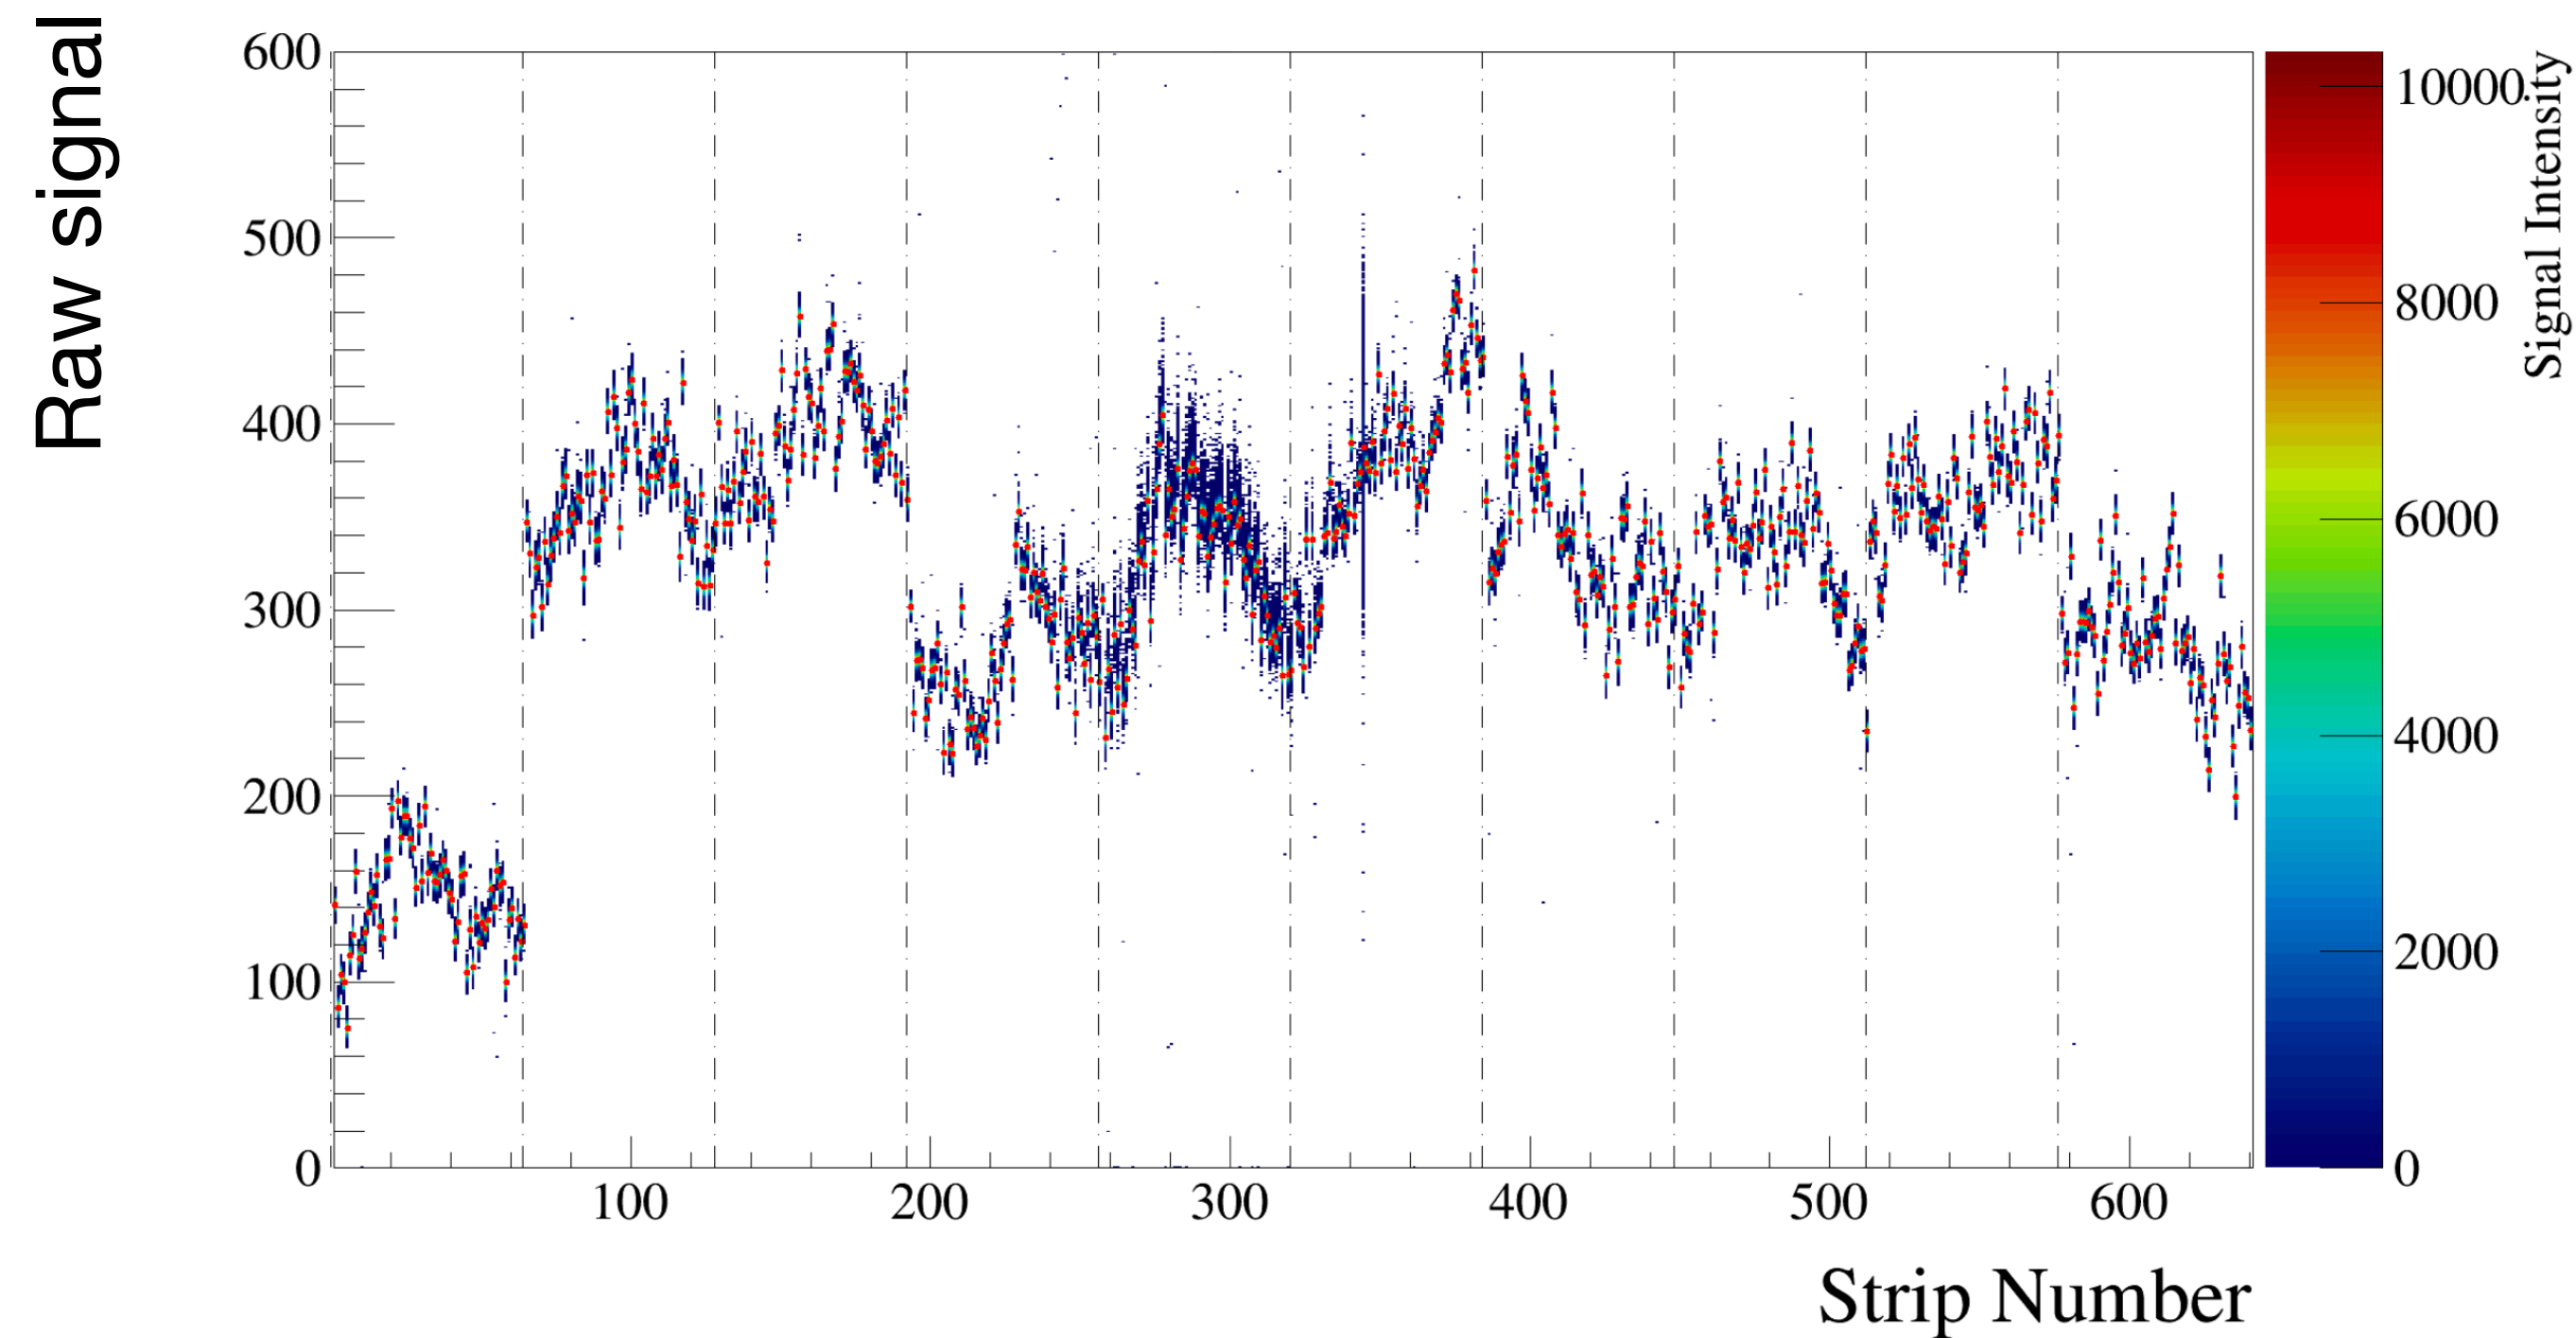

Protons beams:

- 100 MeV
- 430 MeV
- 1000 MeV

# Baseline correction in a single FOOT

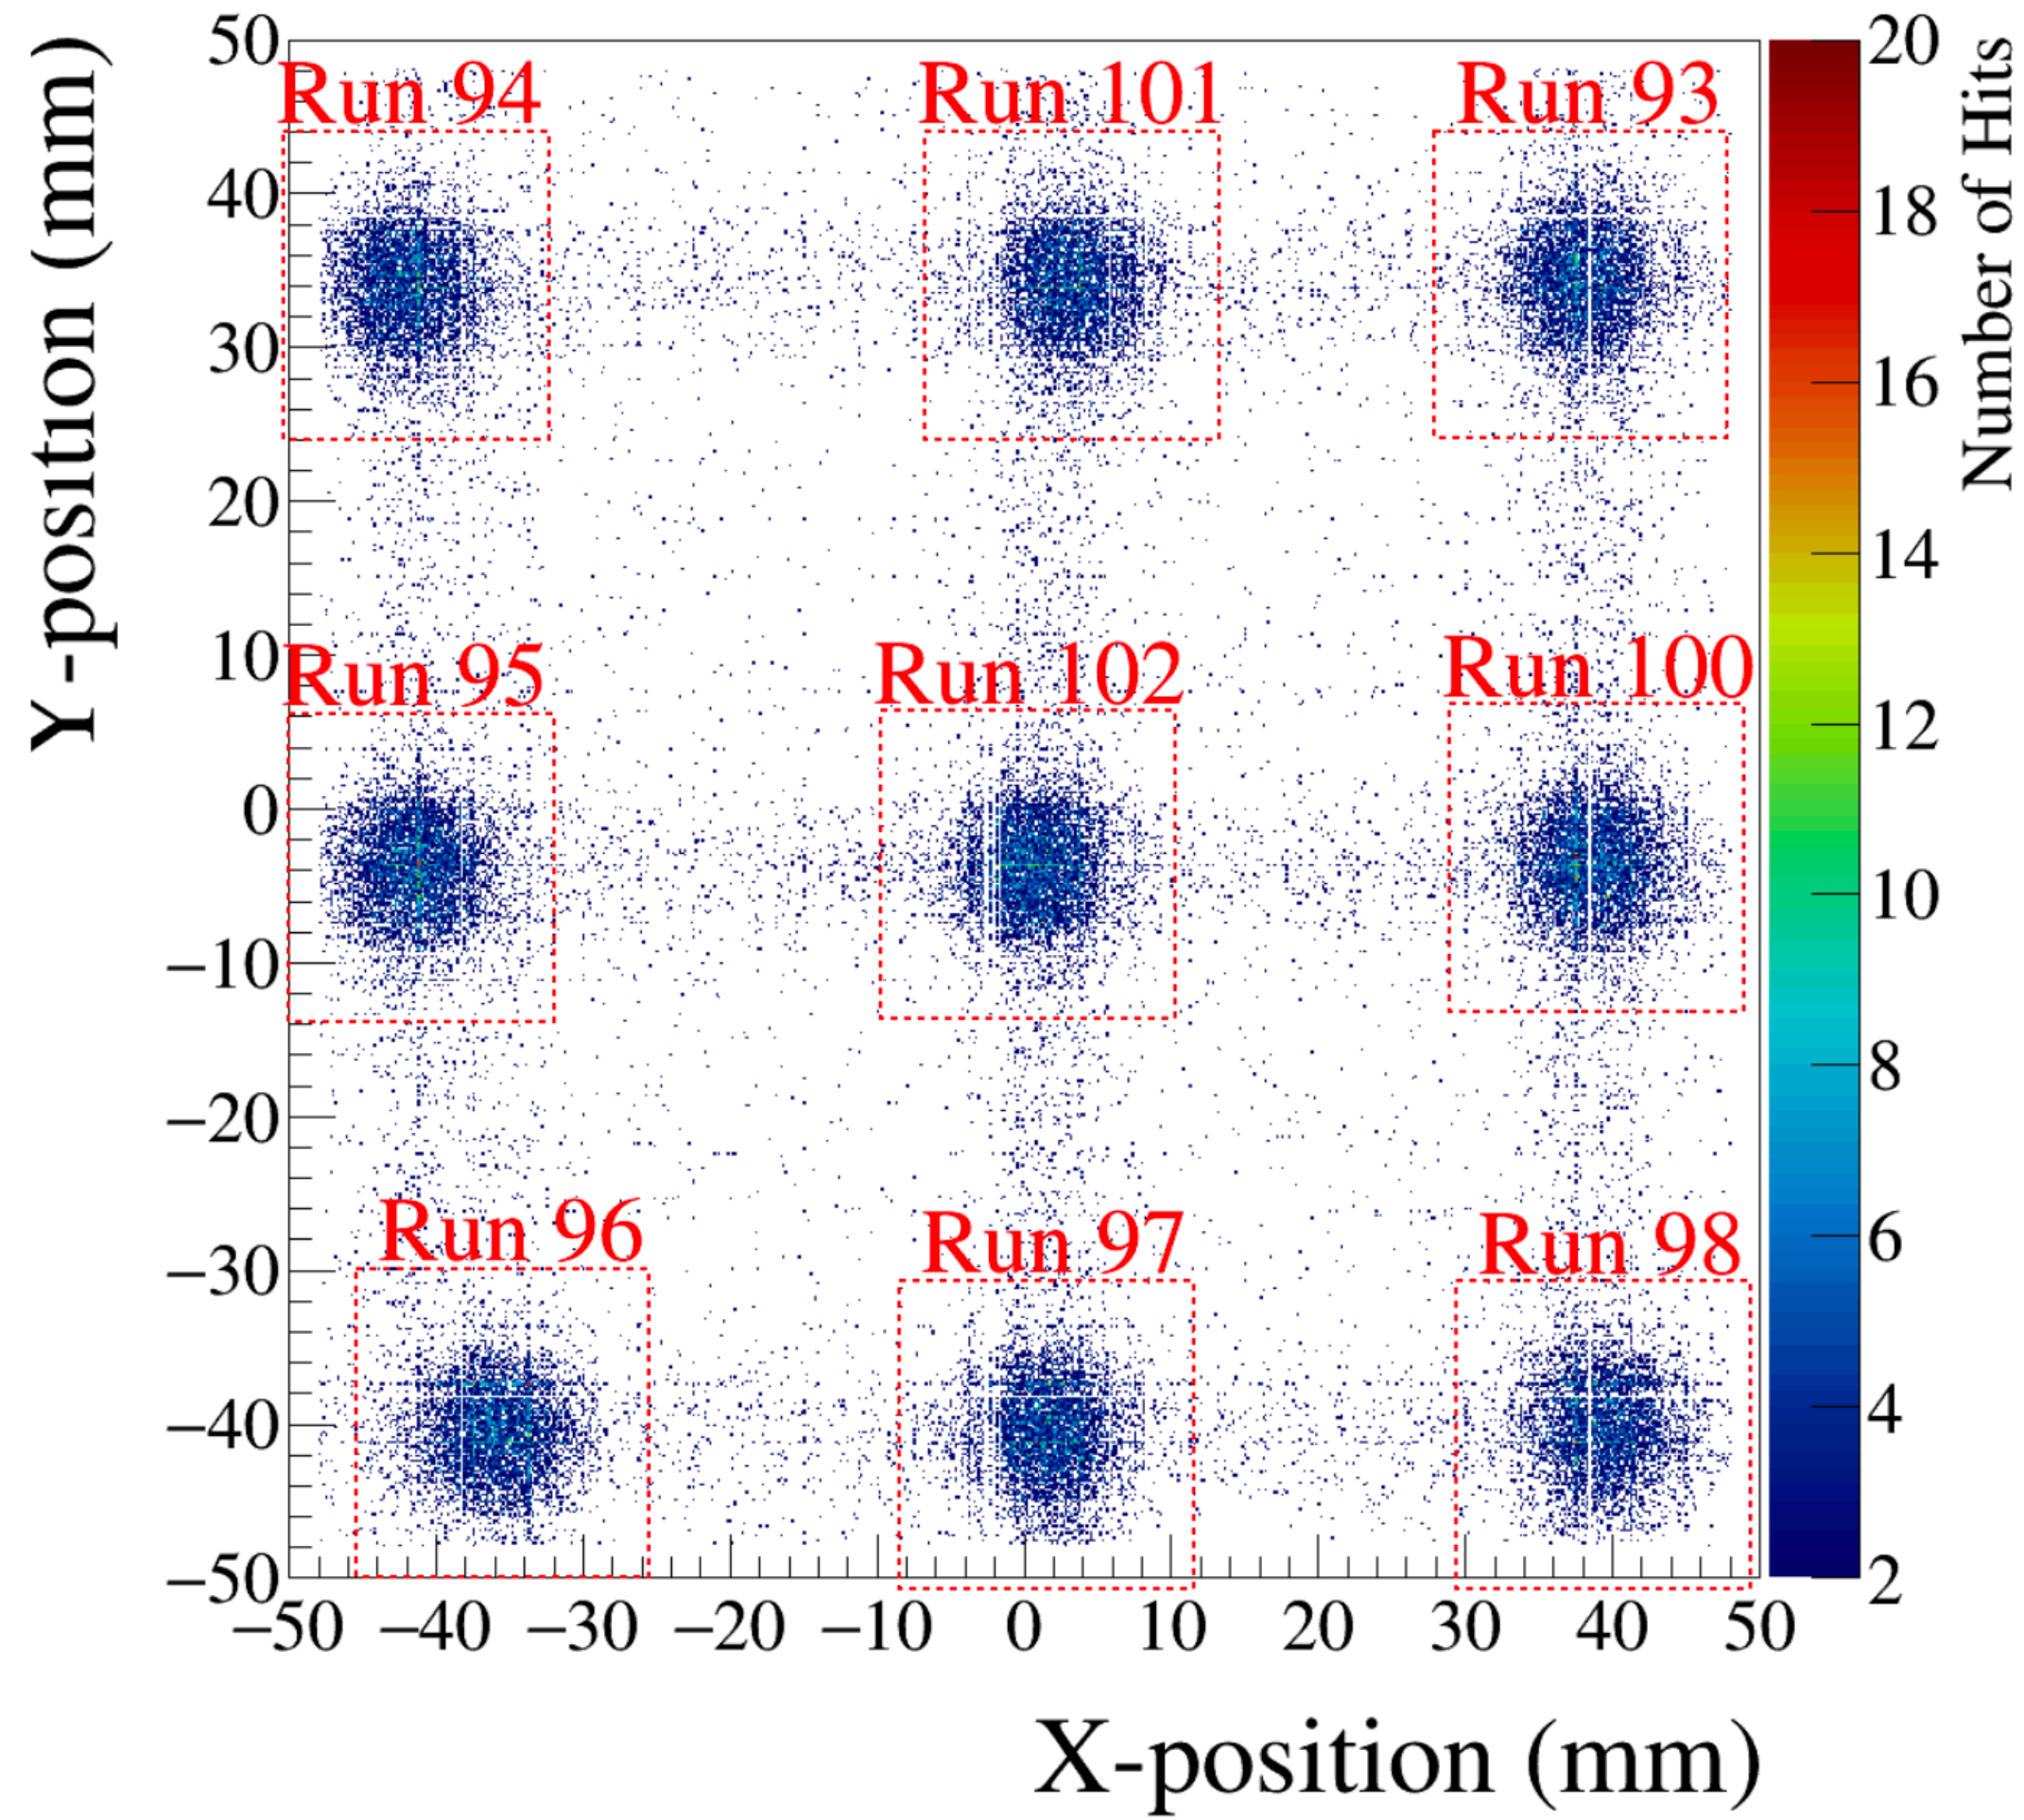

Signal in one strip      raw signal      pedestal      ASIC common offset

$$S_i = A_i - P_i - M_{ASIC} \longrightarrow M_{ASIC} = \sum_{k=1}^N \frac{(A_k - P_k)}{N} \quad \text{- fine correction event by event}$$

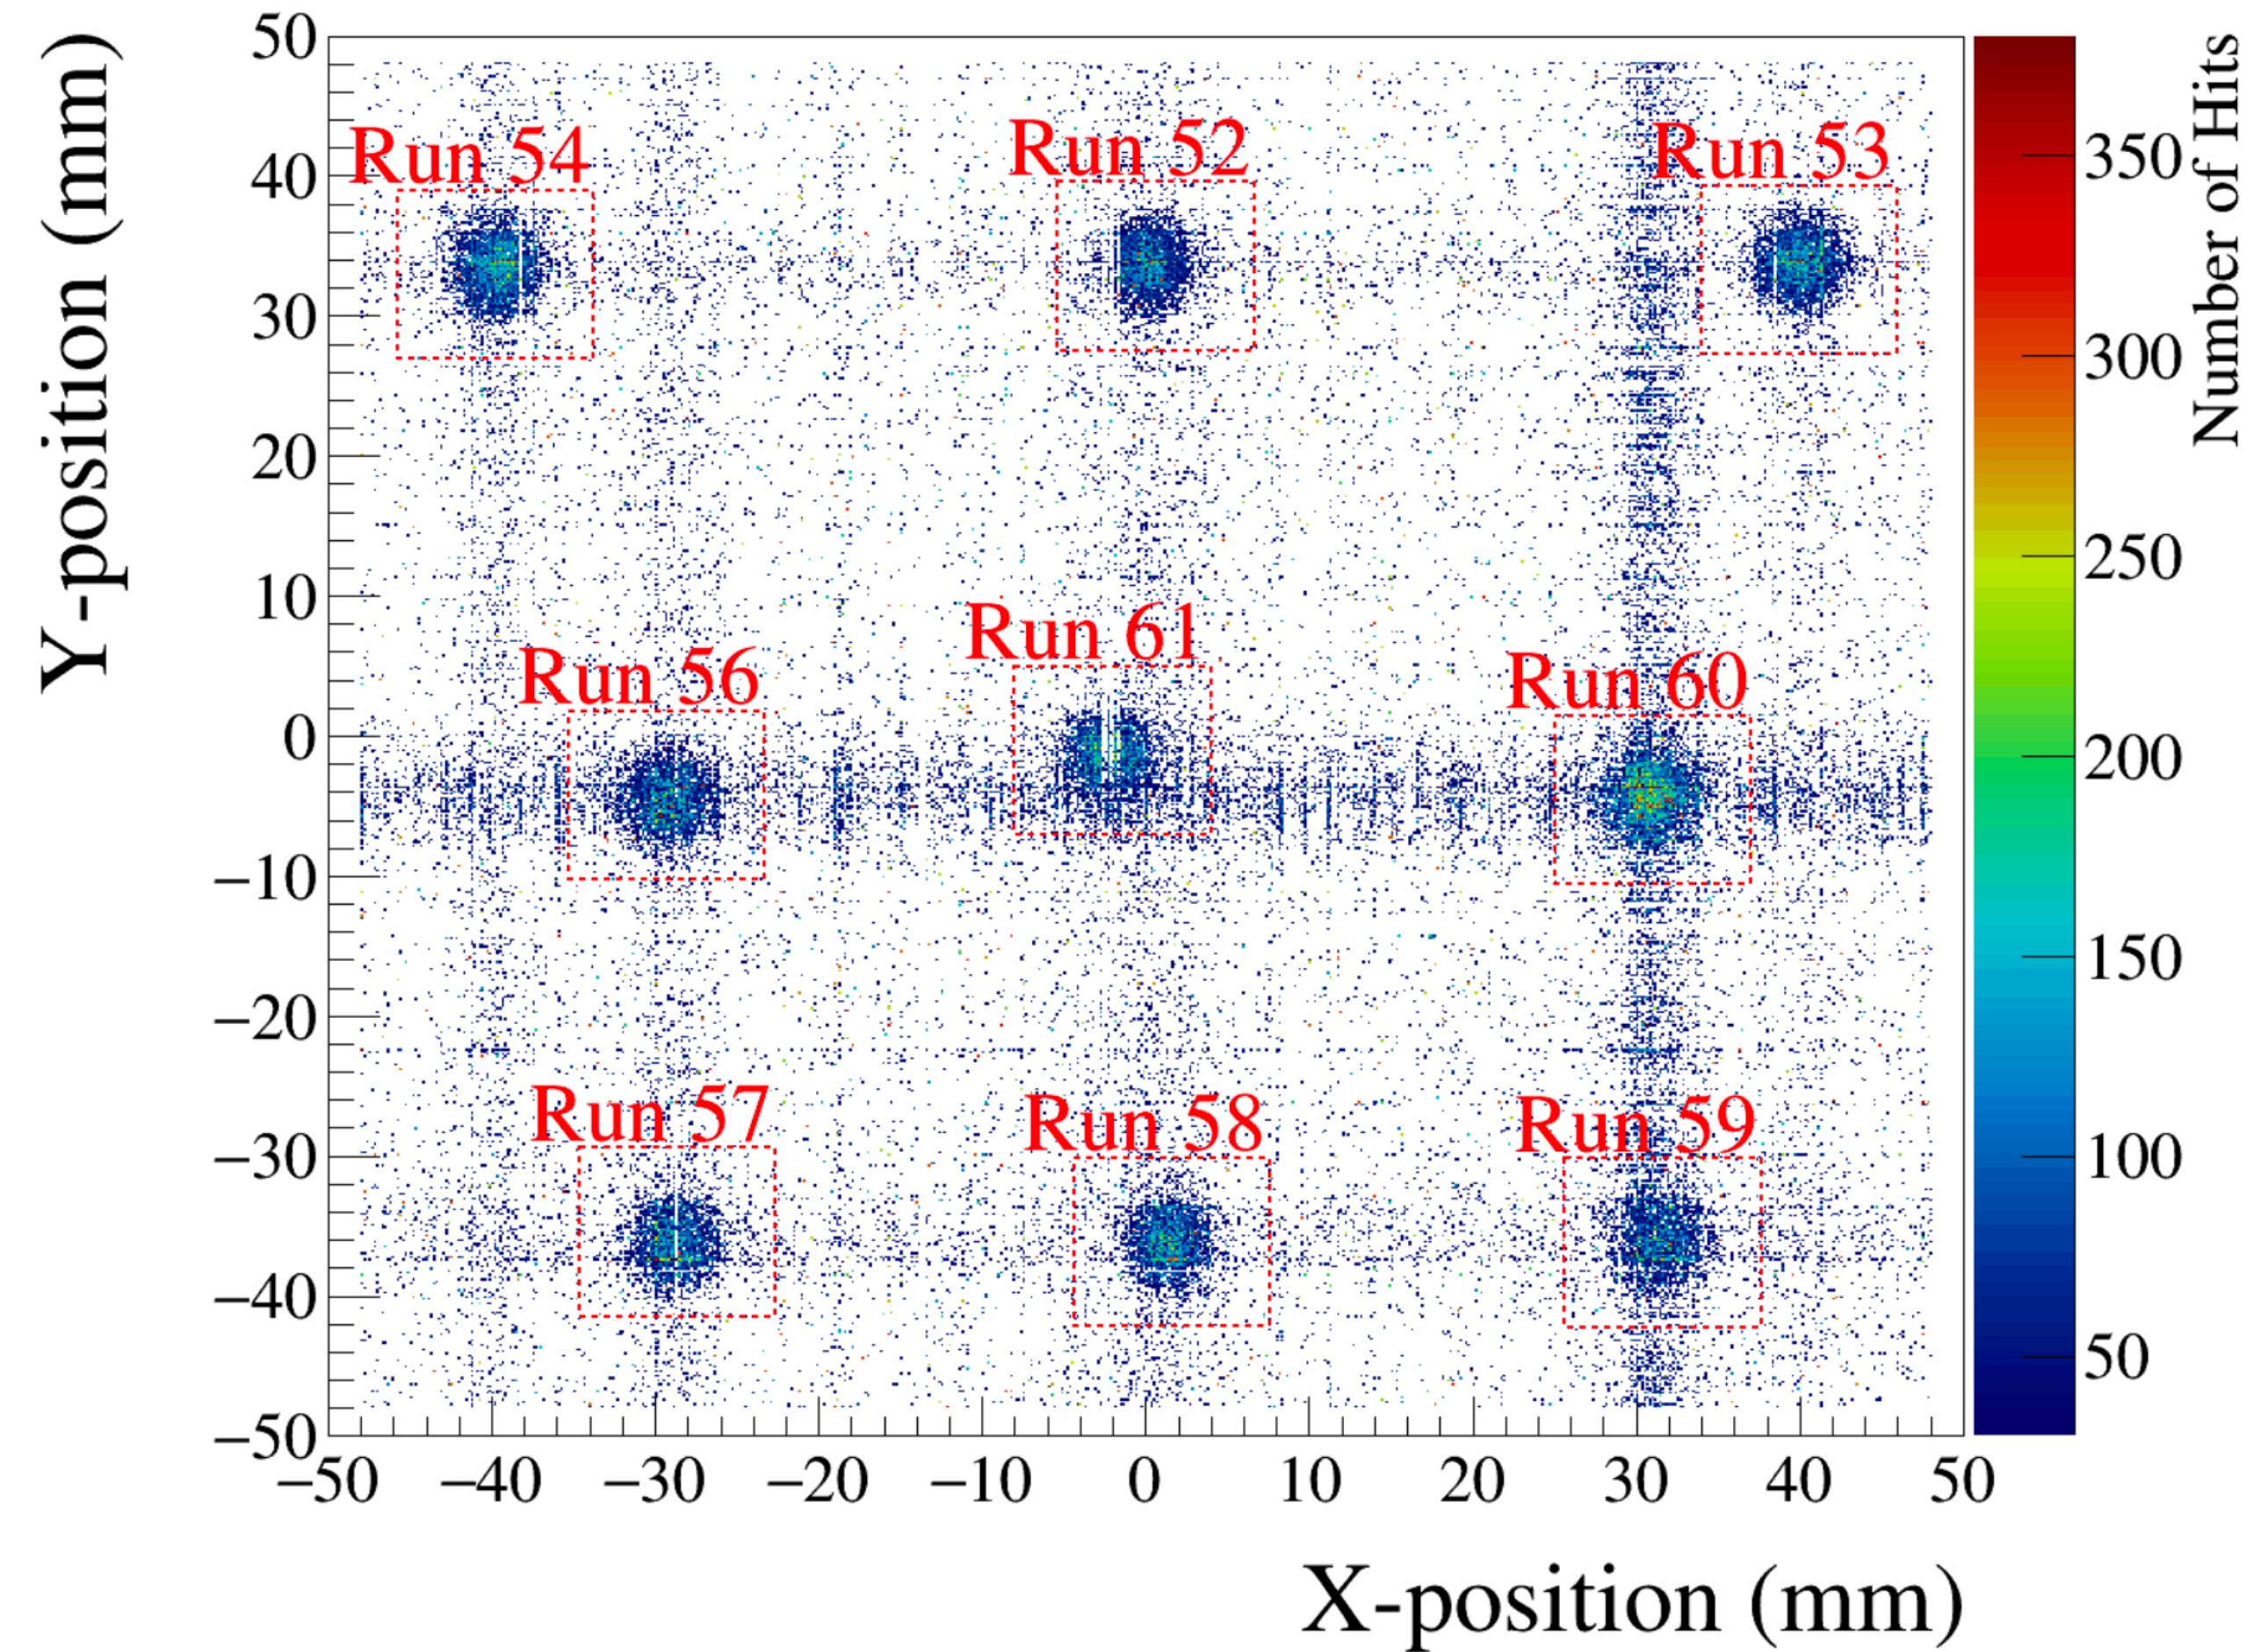

# 430 MeV protons

20 kHz beam

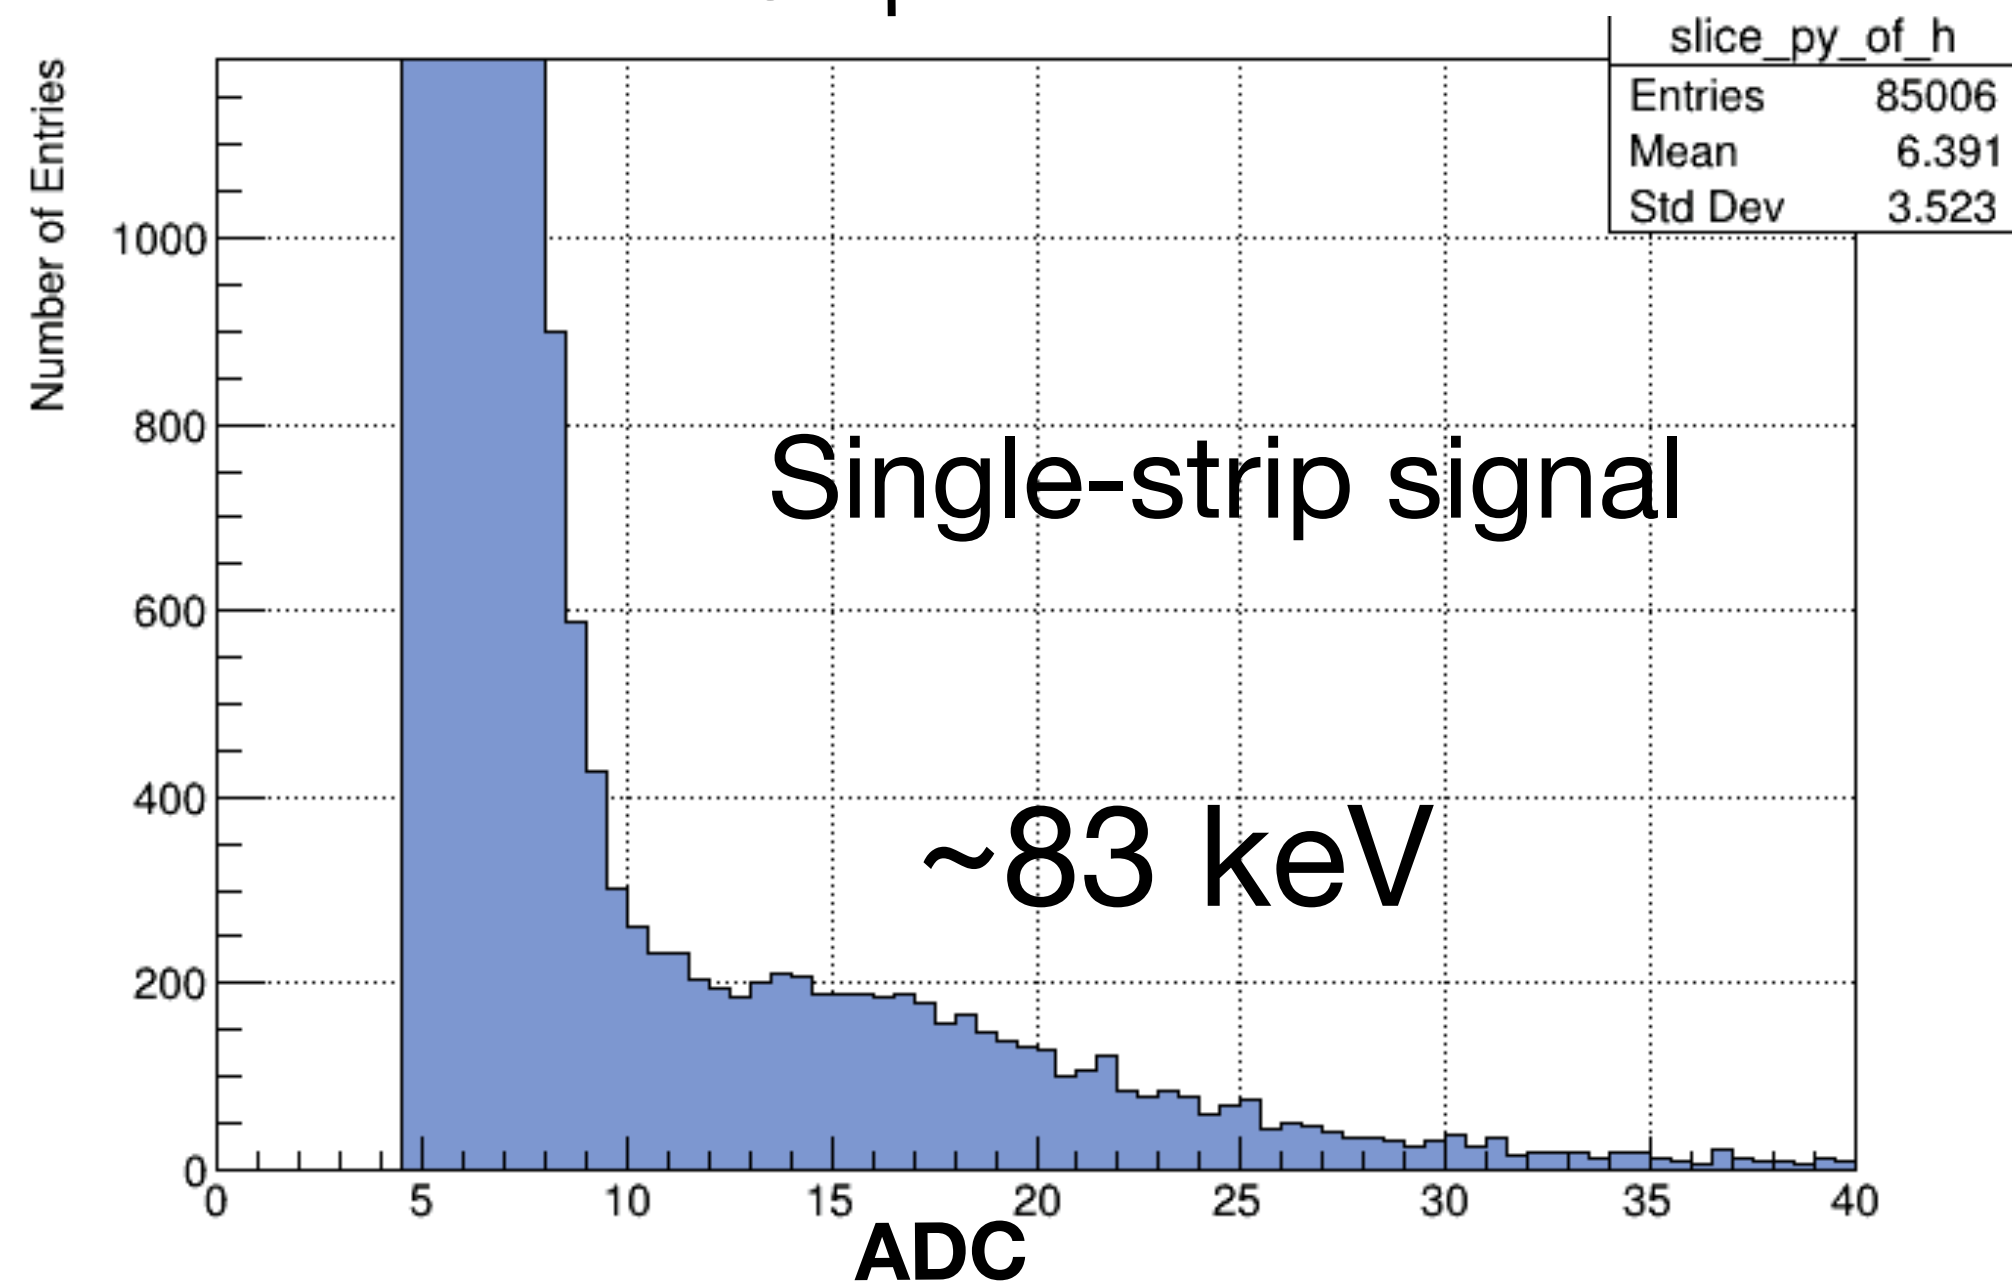

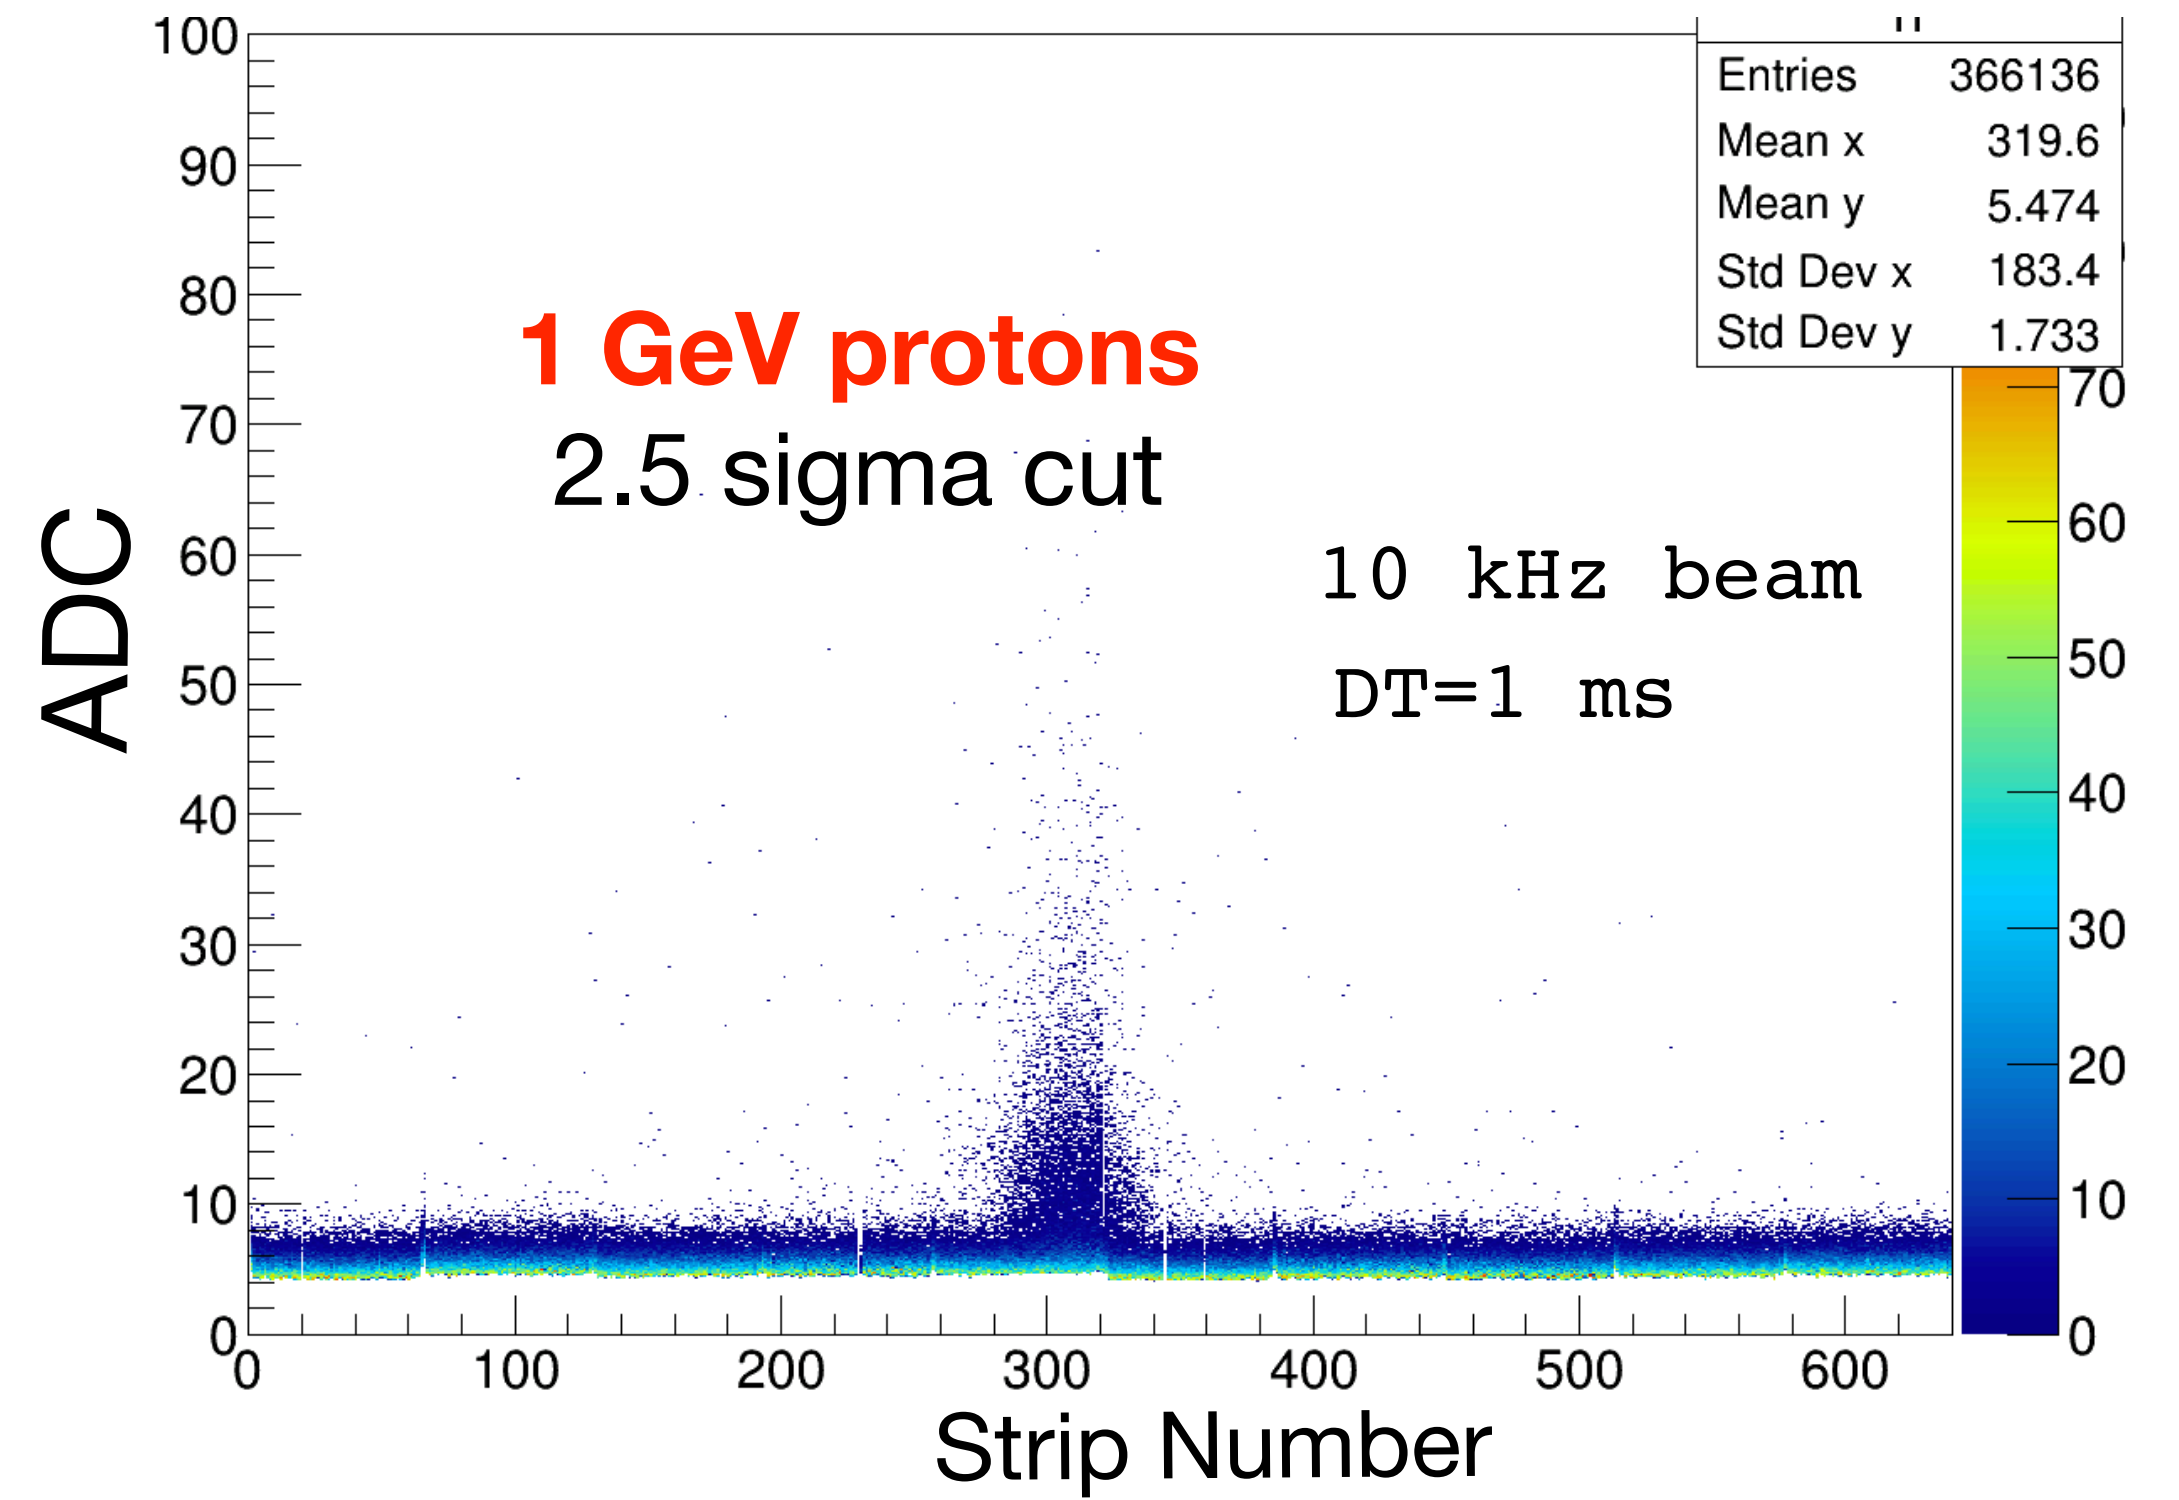

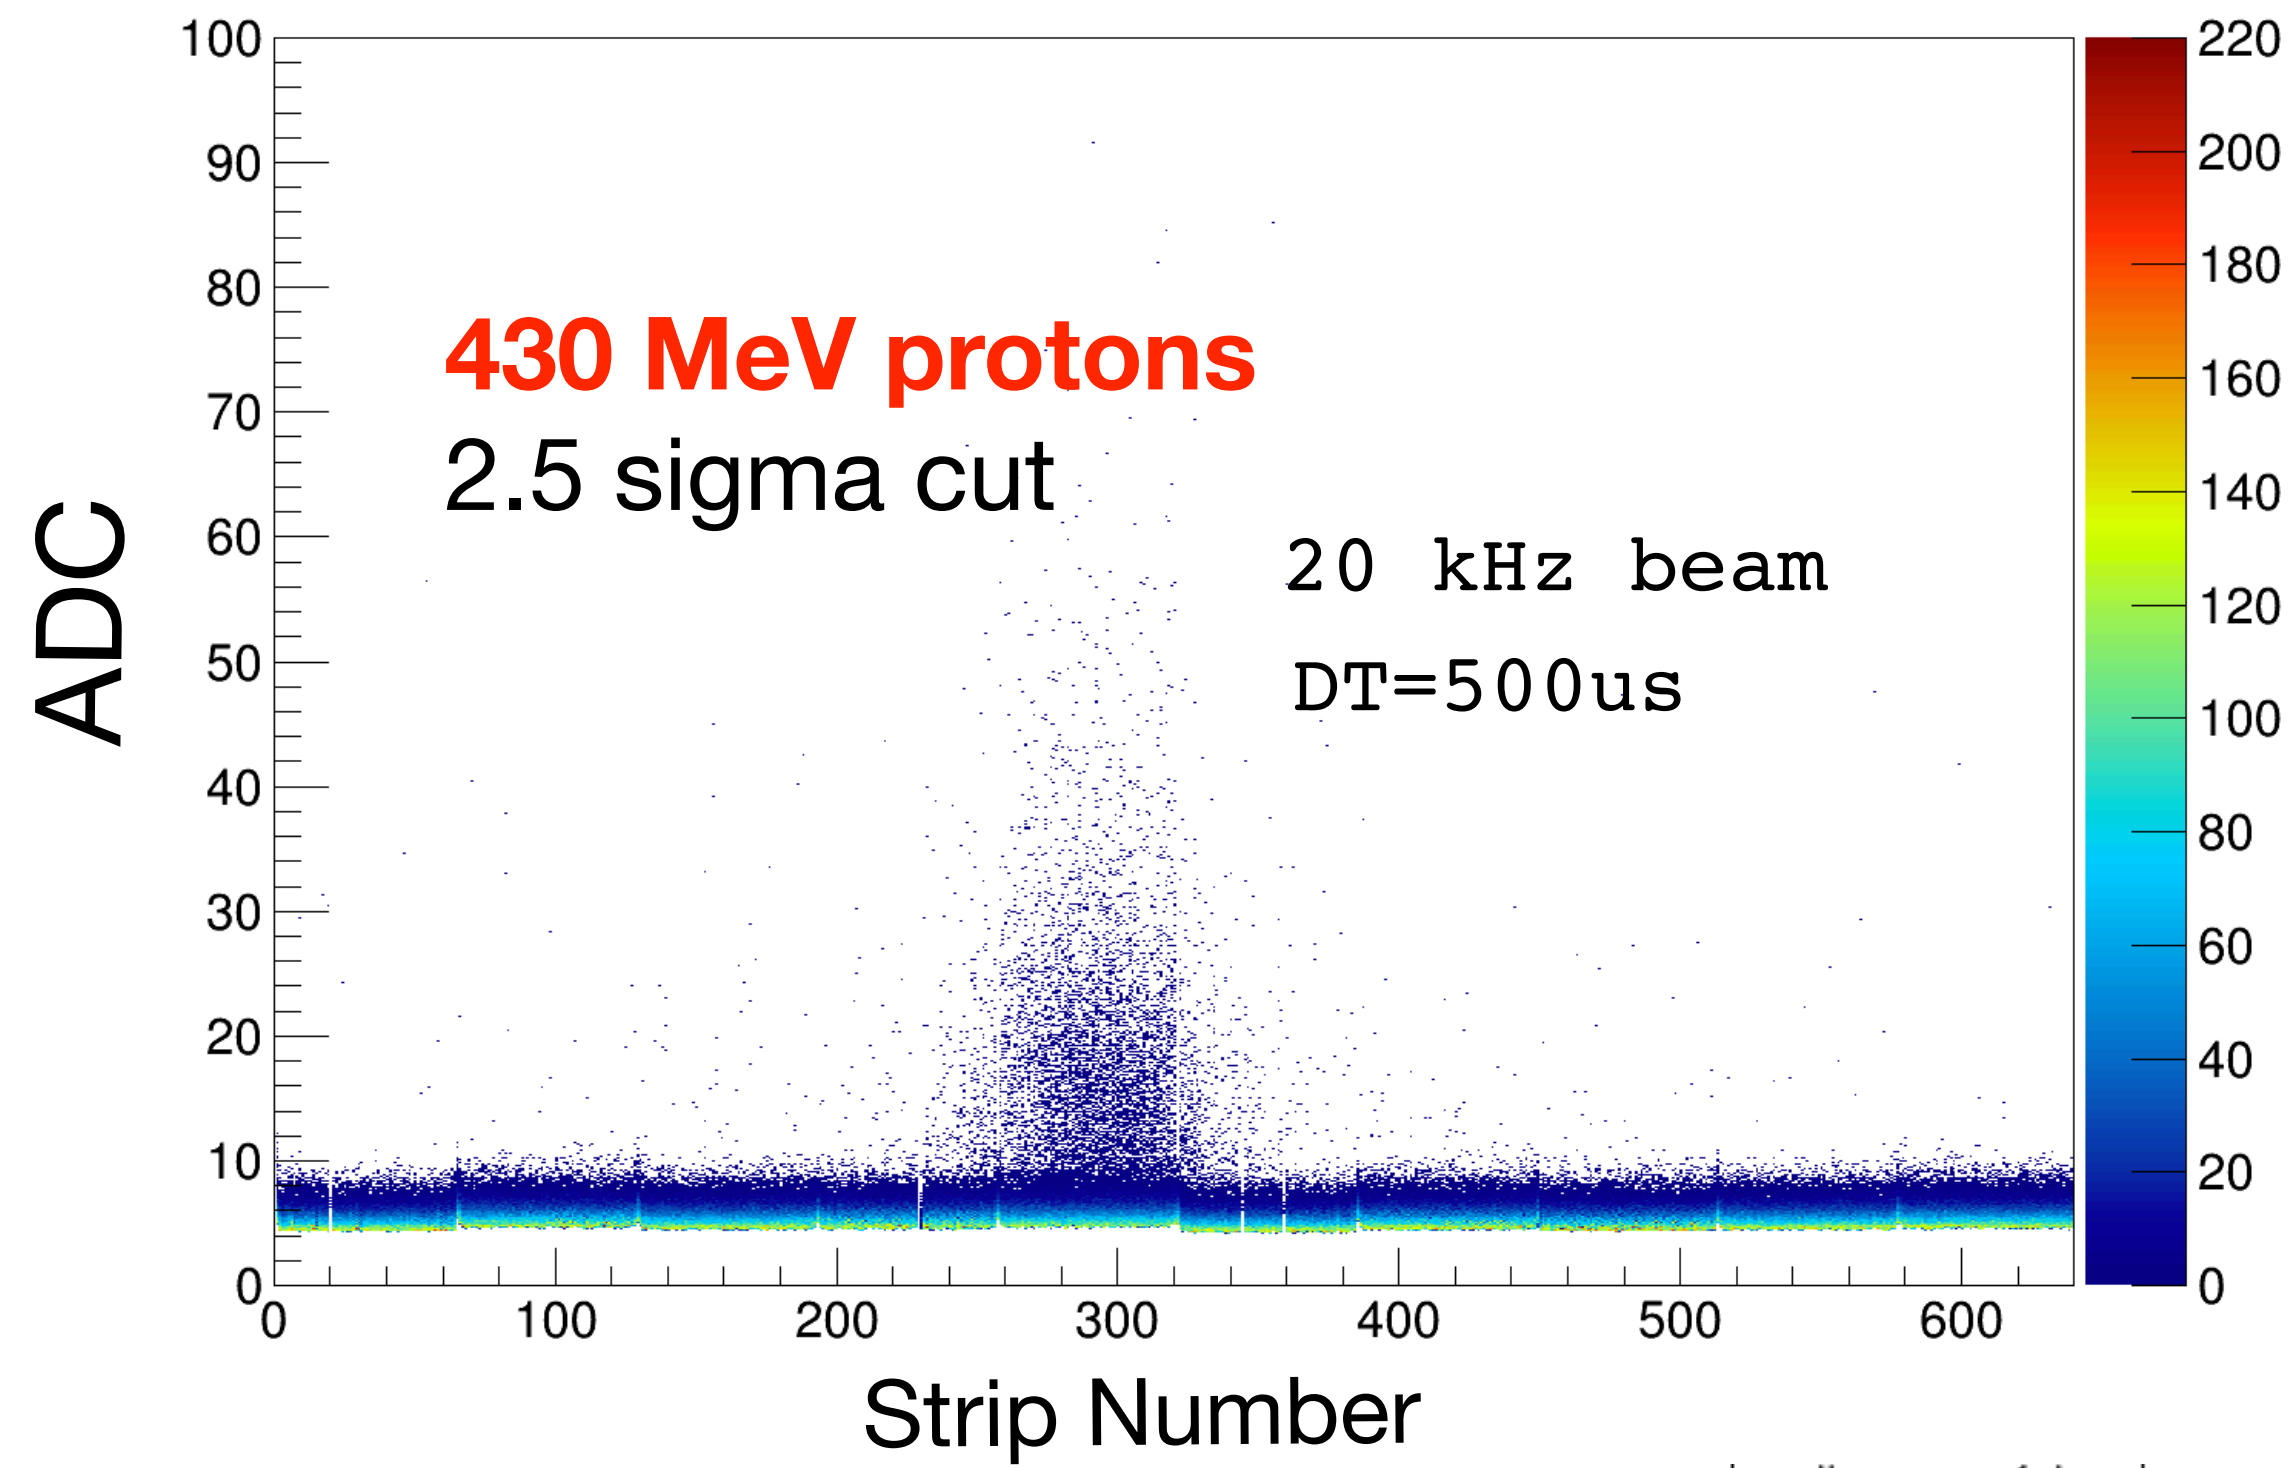

# 1000 MeV protons

10 kHz beam

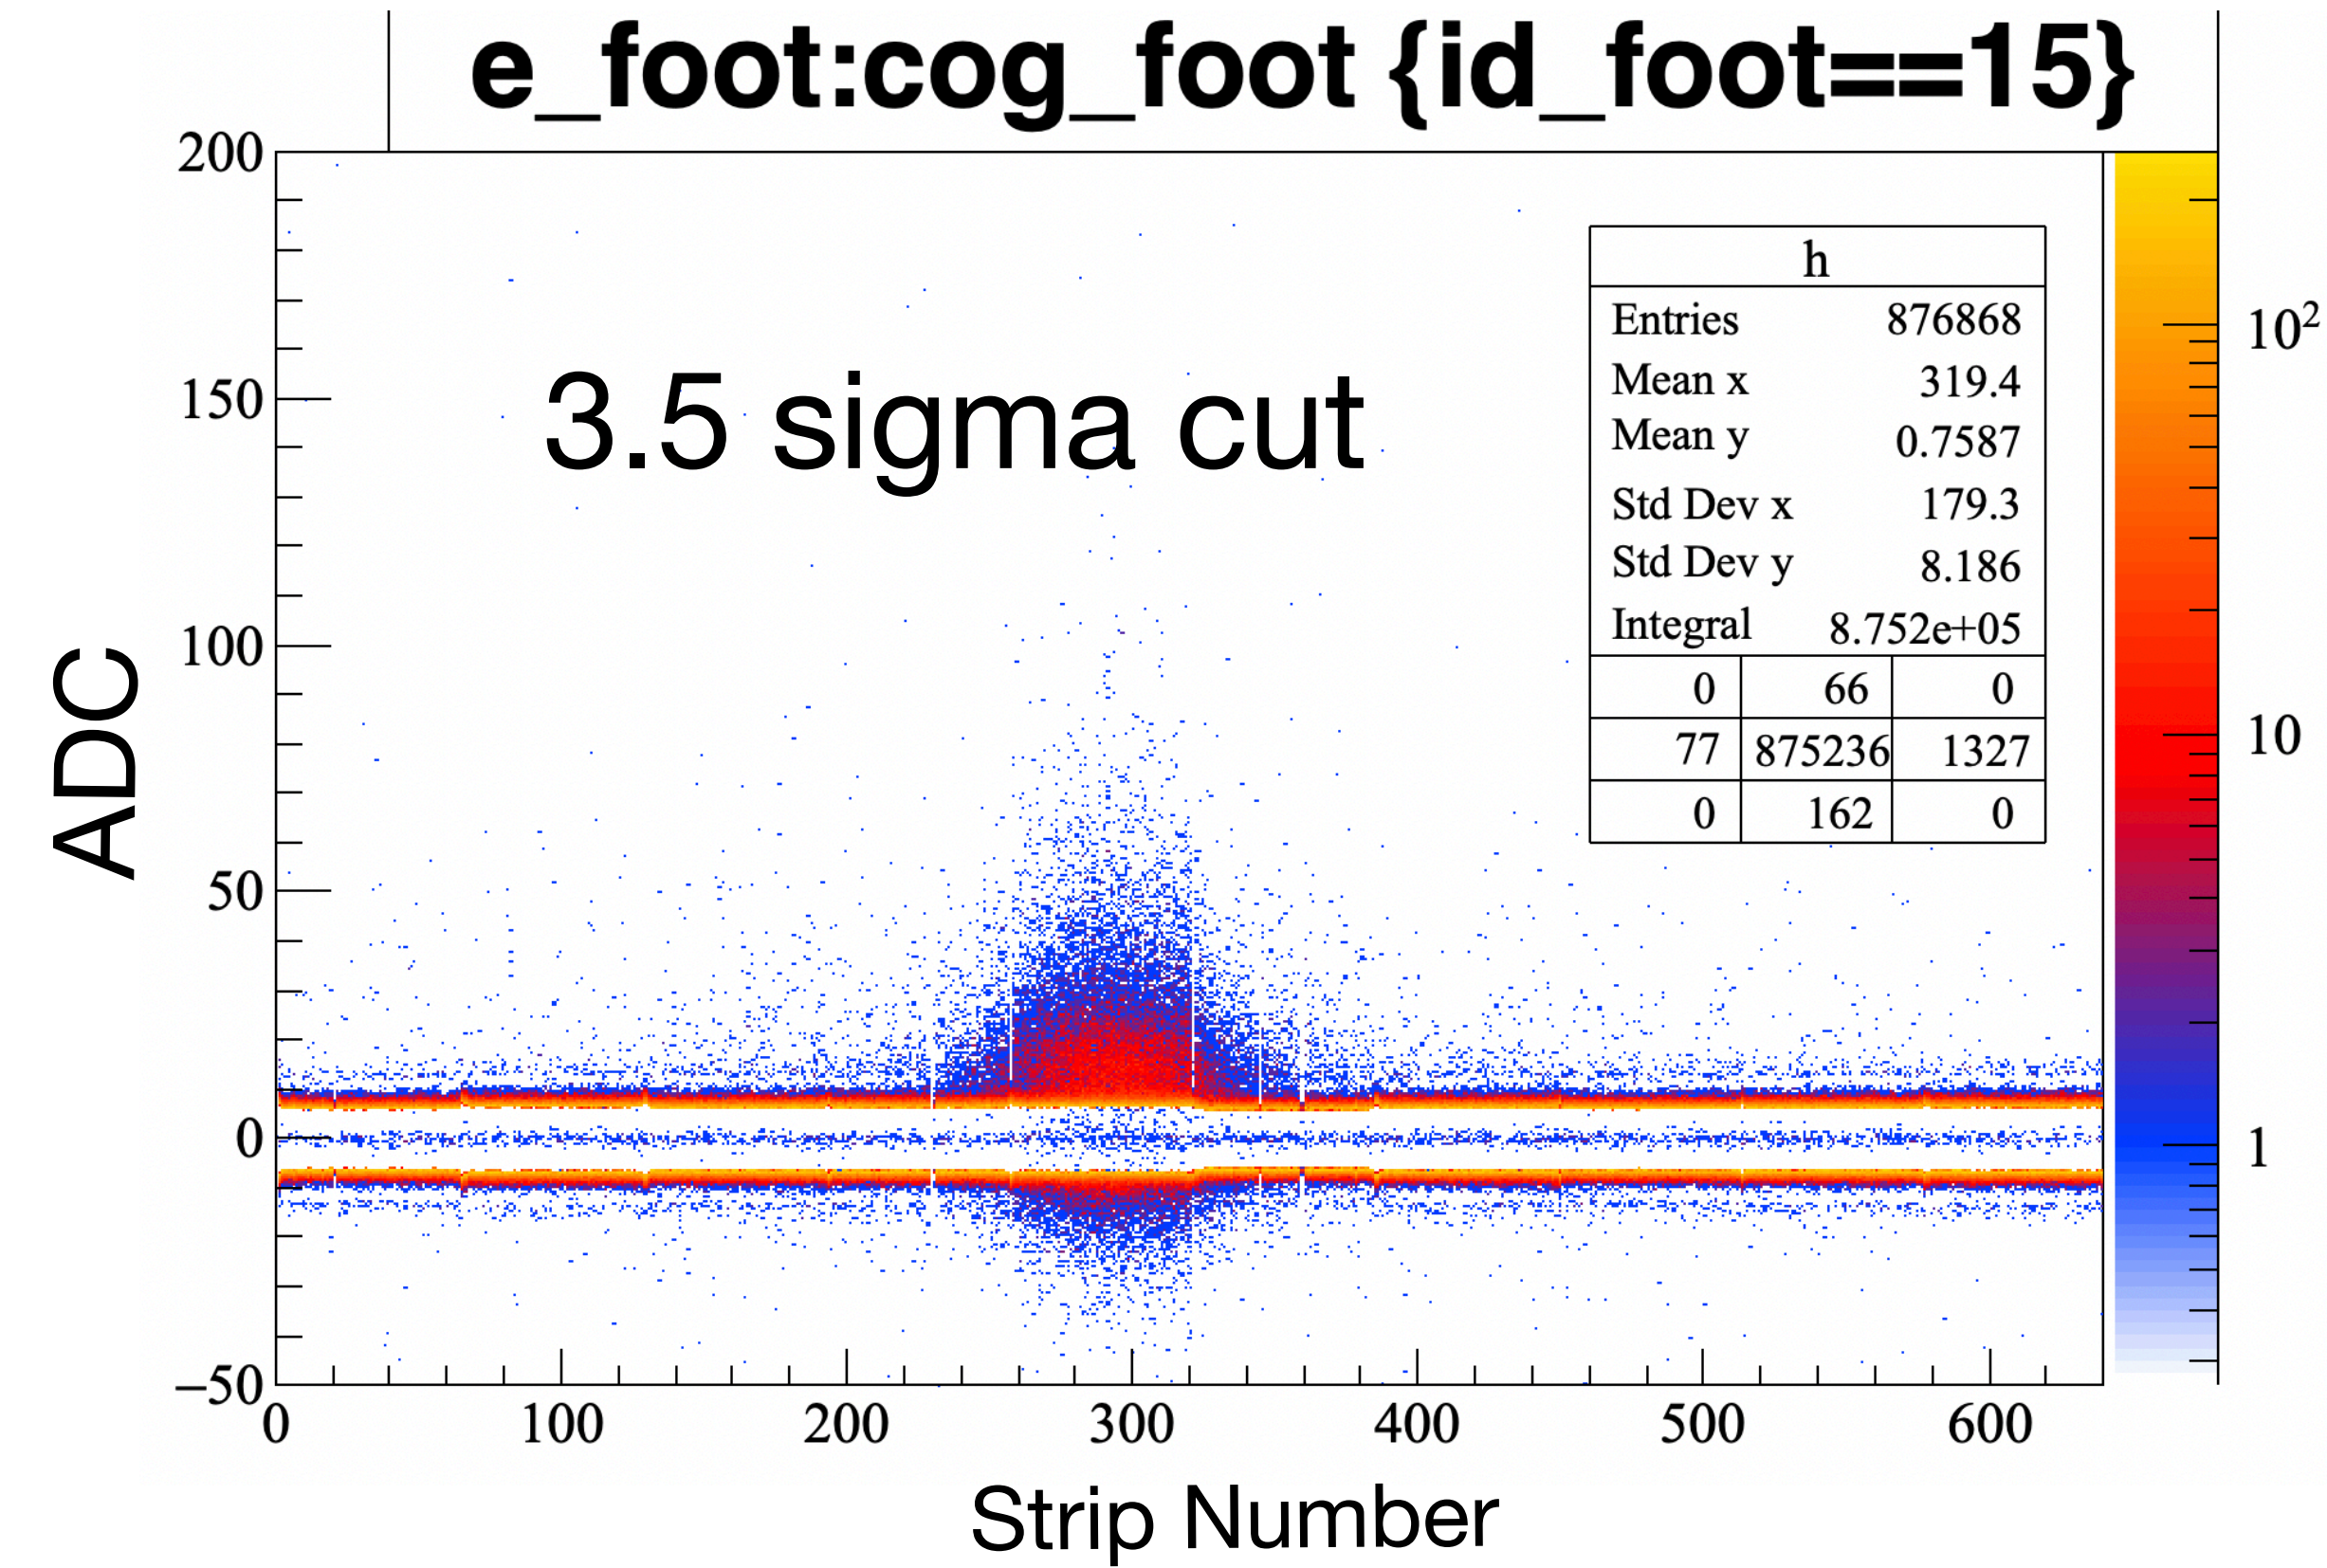

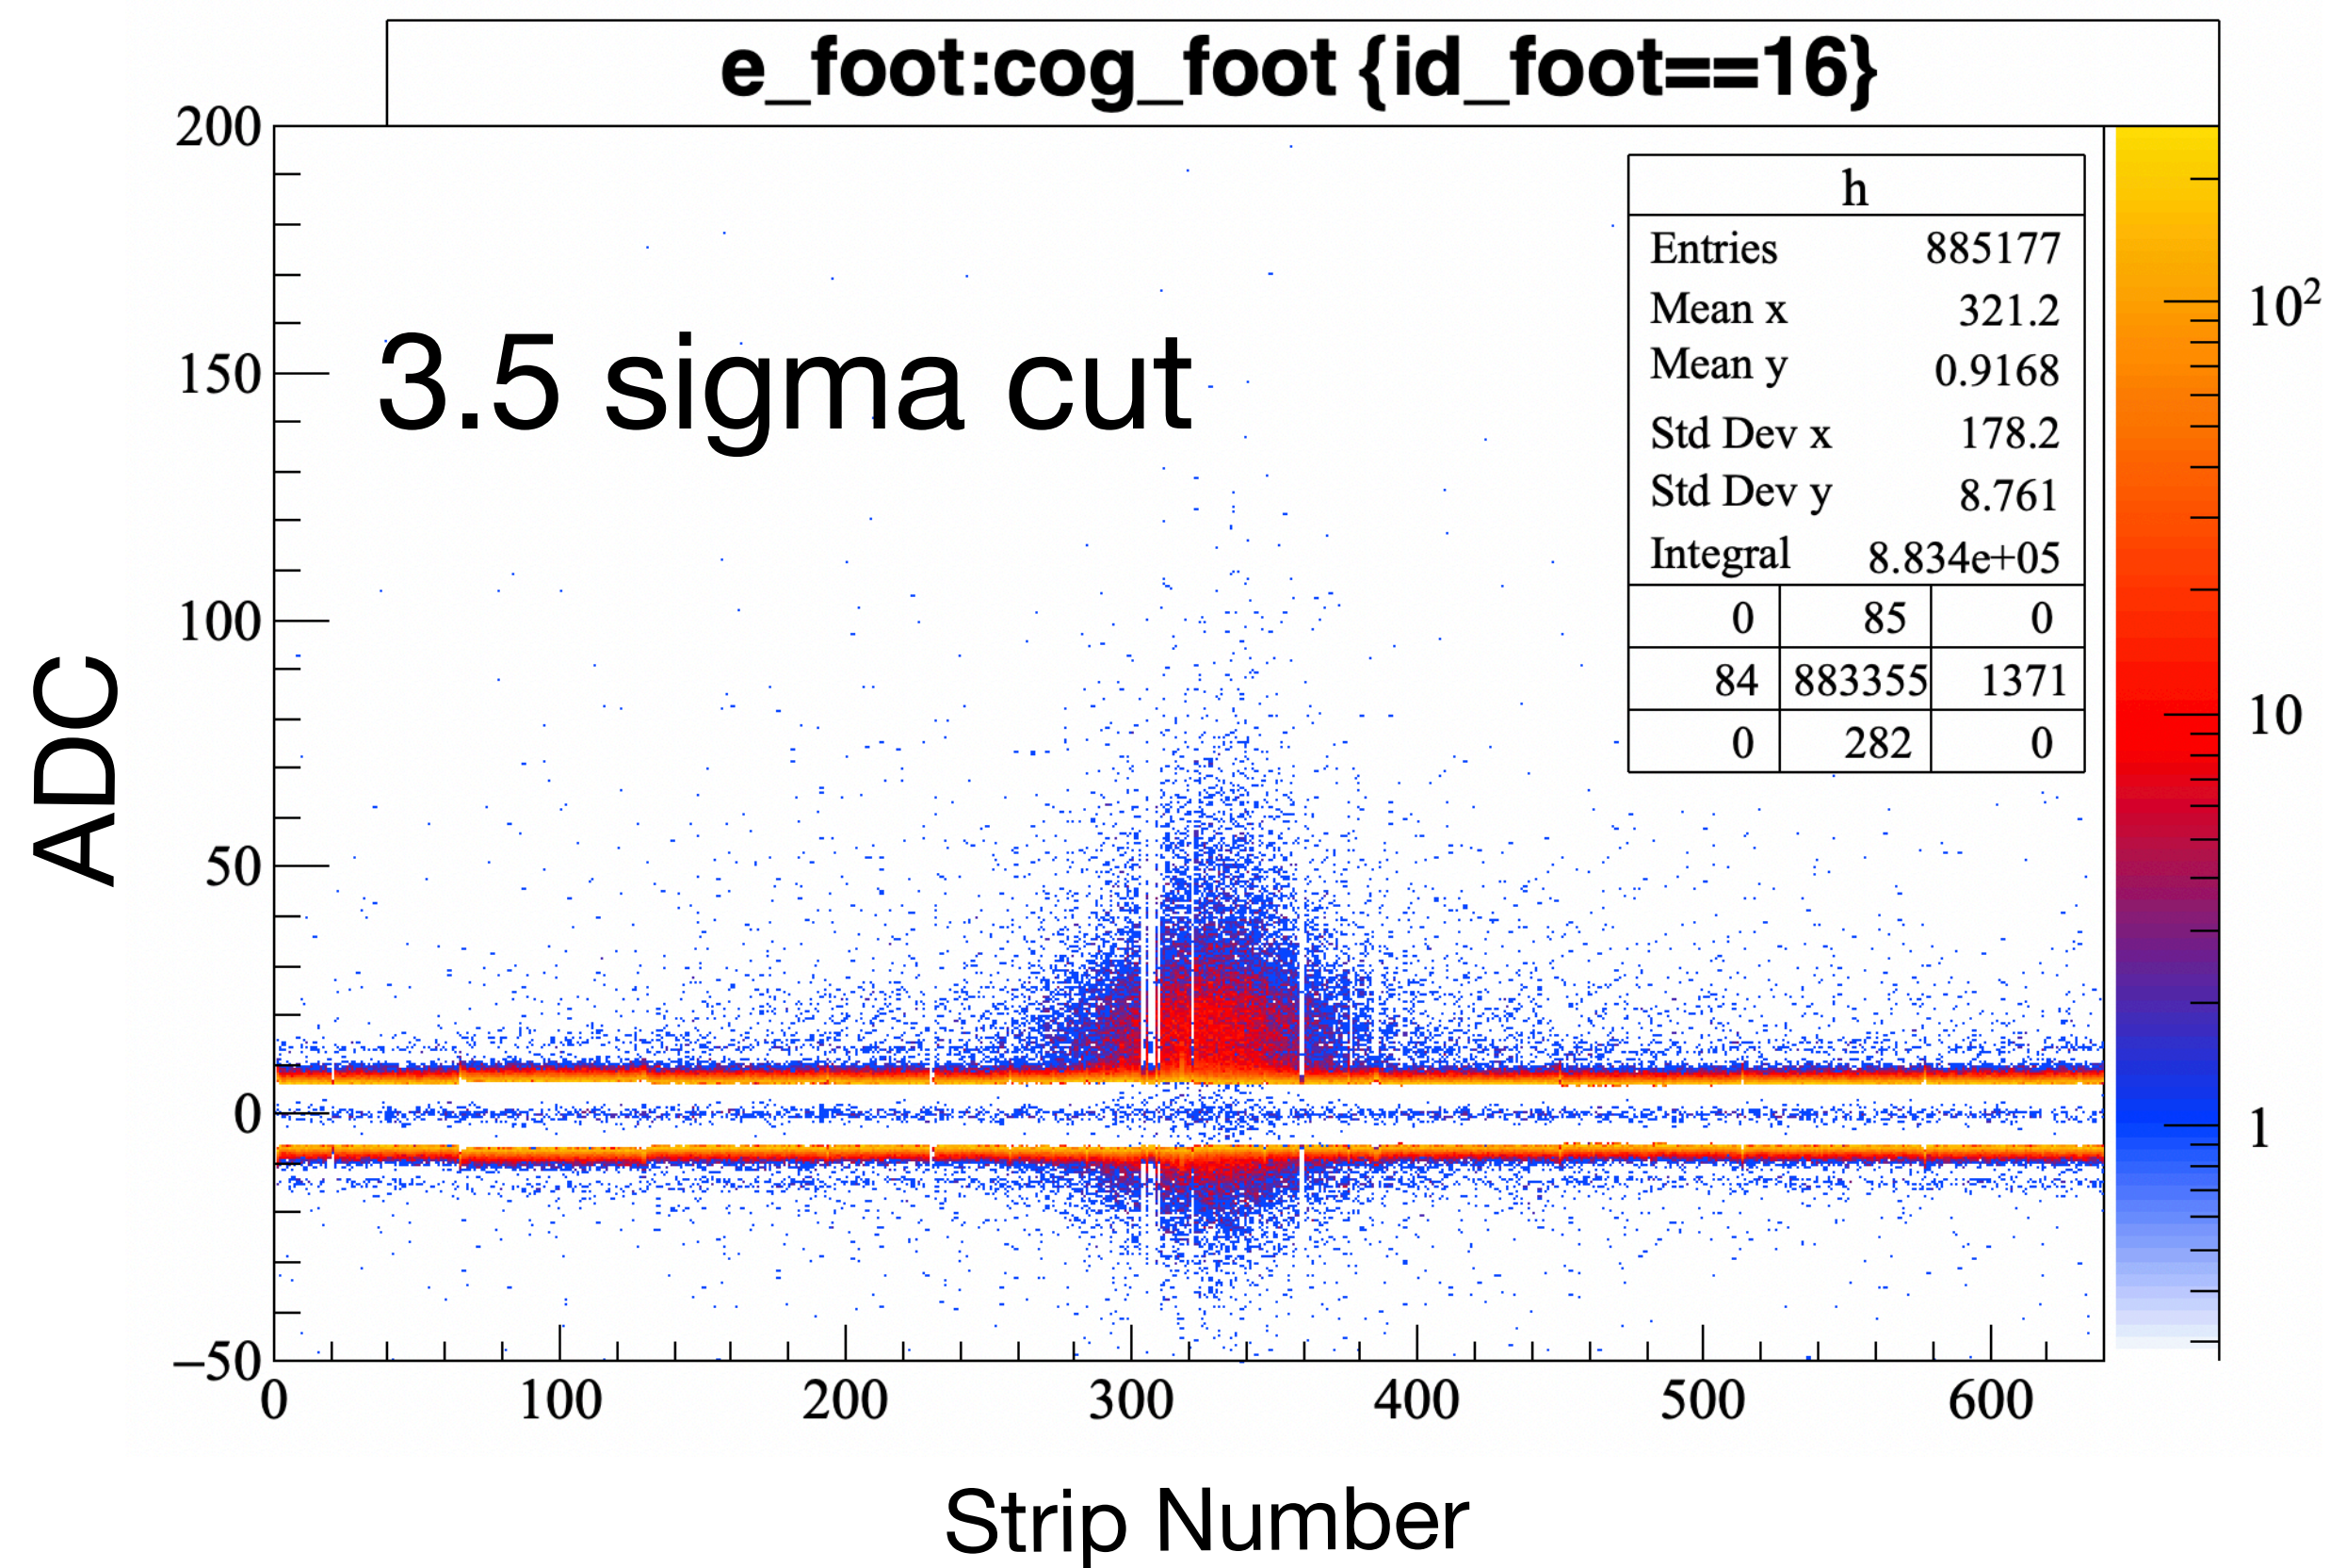

5 sigma threshold

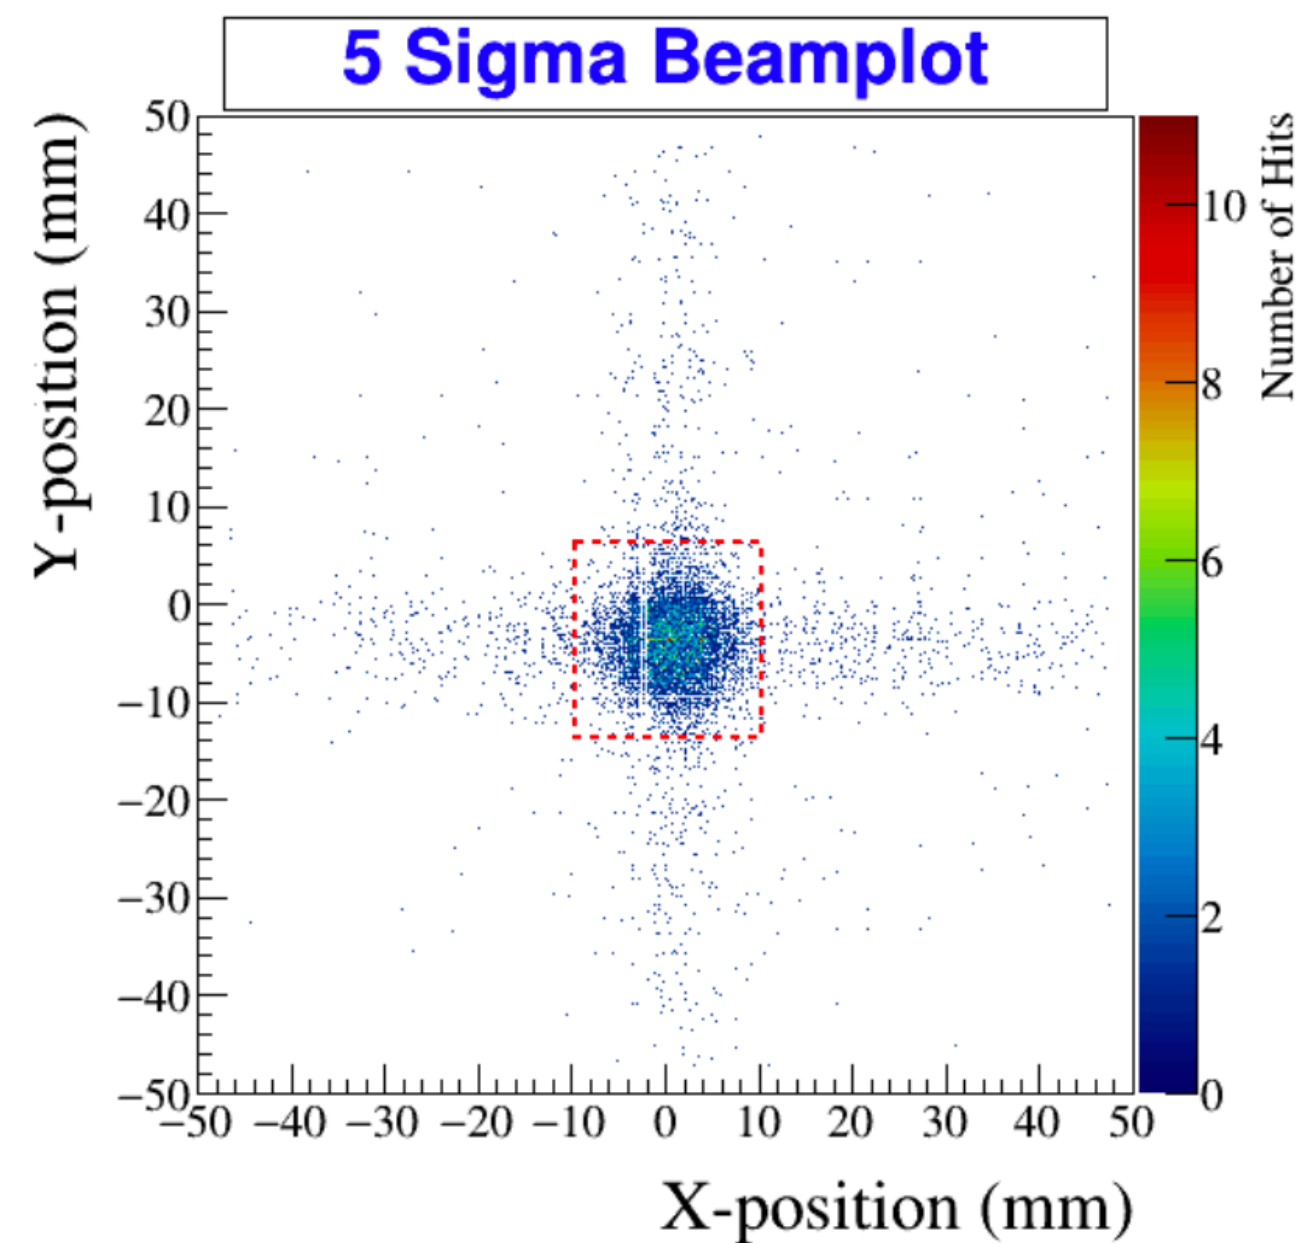

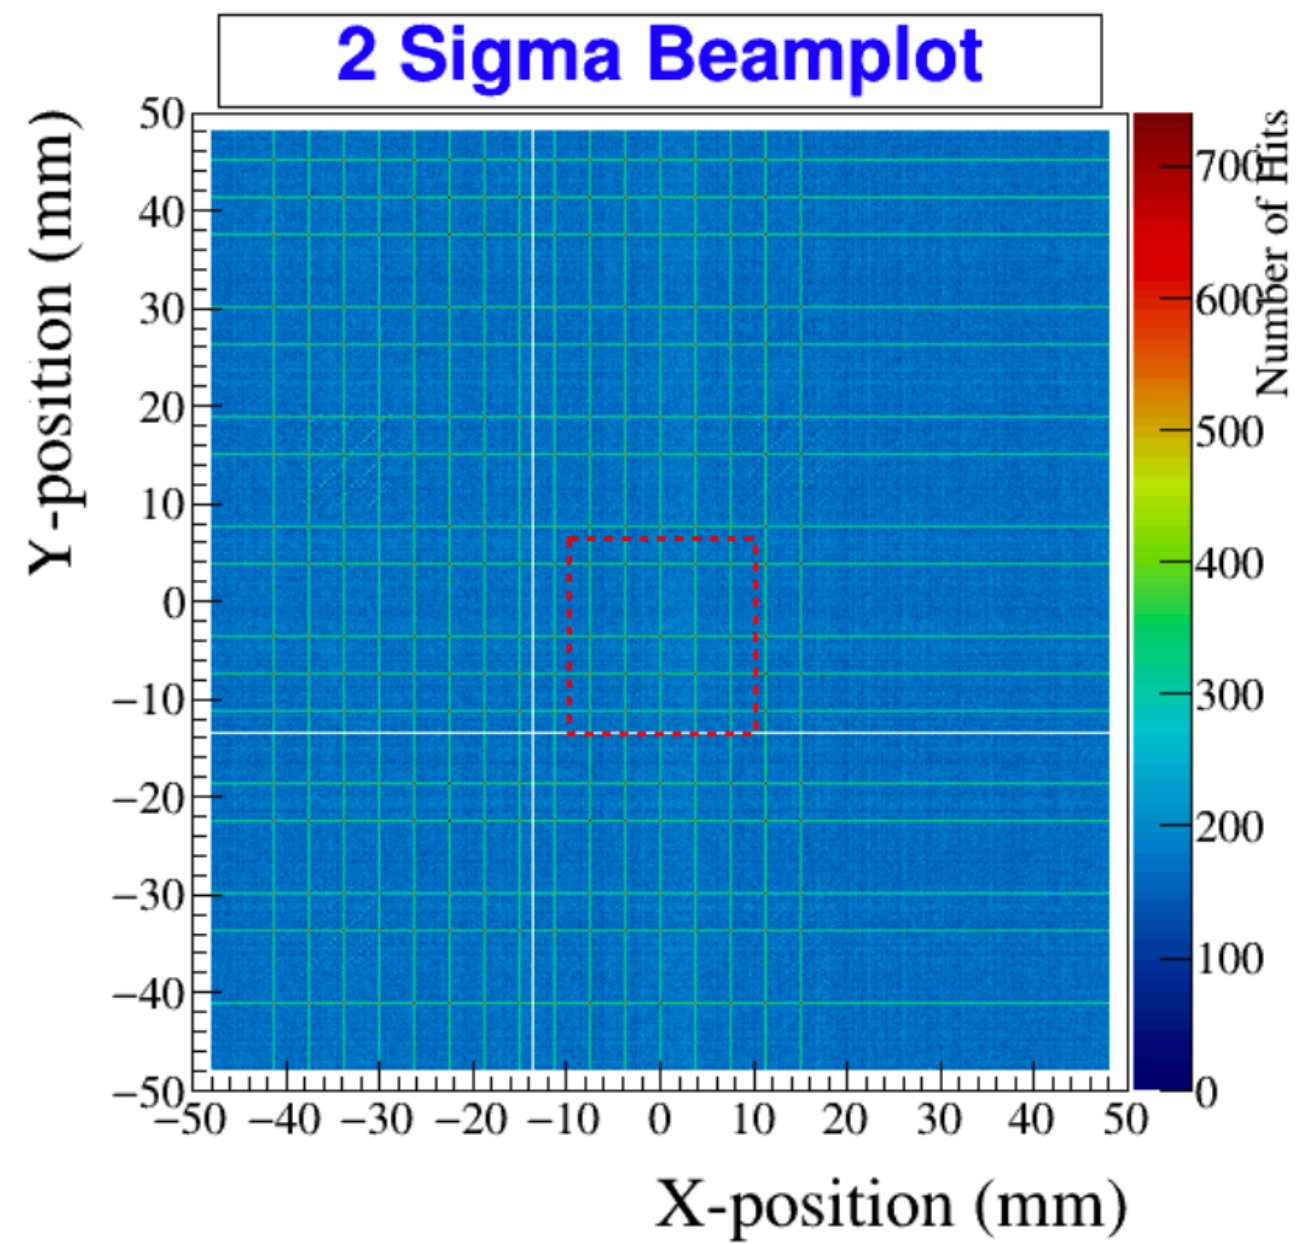

# 430 MeV protons

clustering with negative signals

# 430 MeV proton beam, different Nsigma threshold

Efficiency calculation:

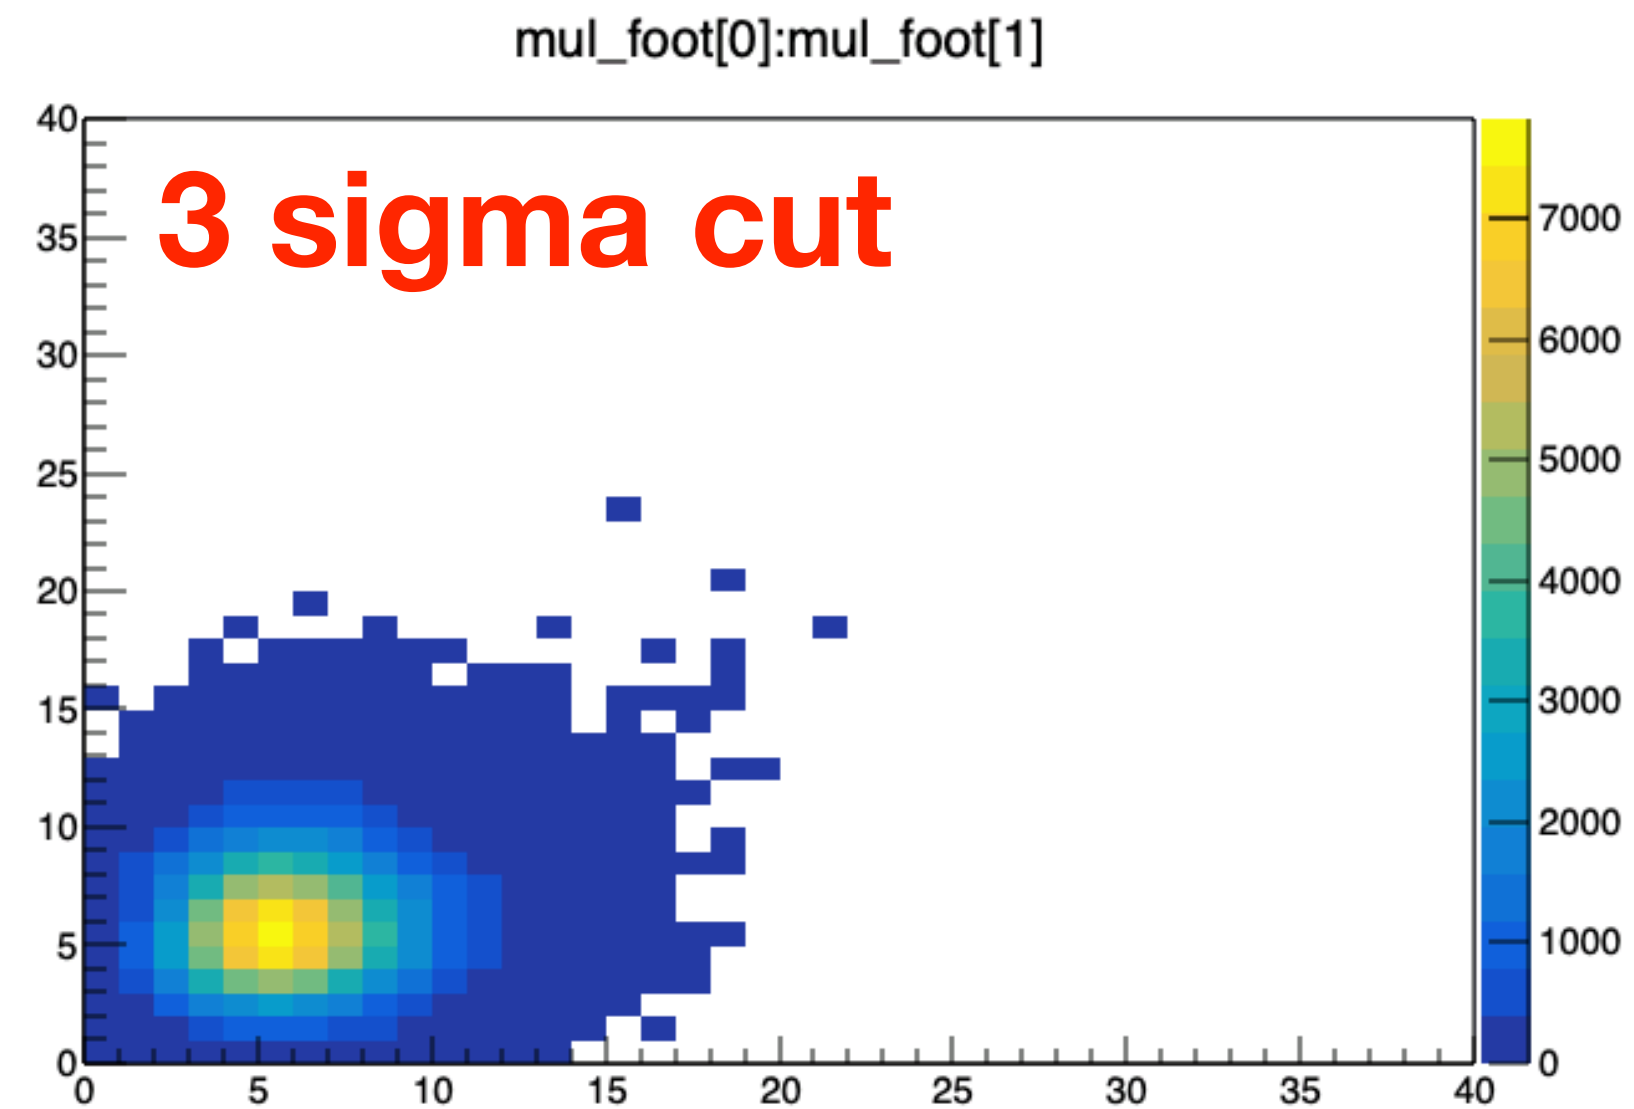

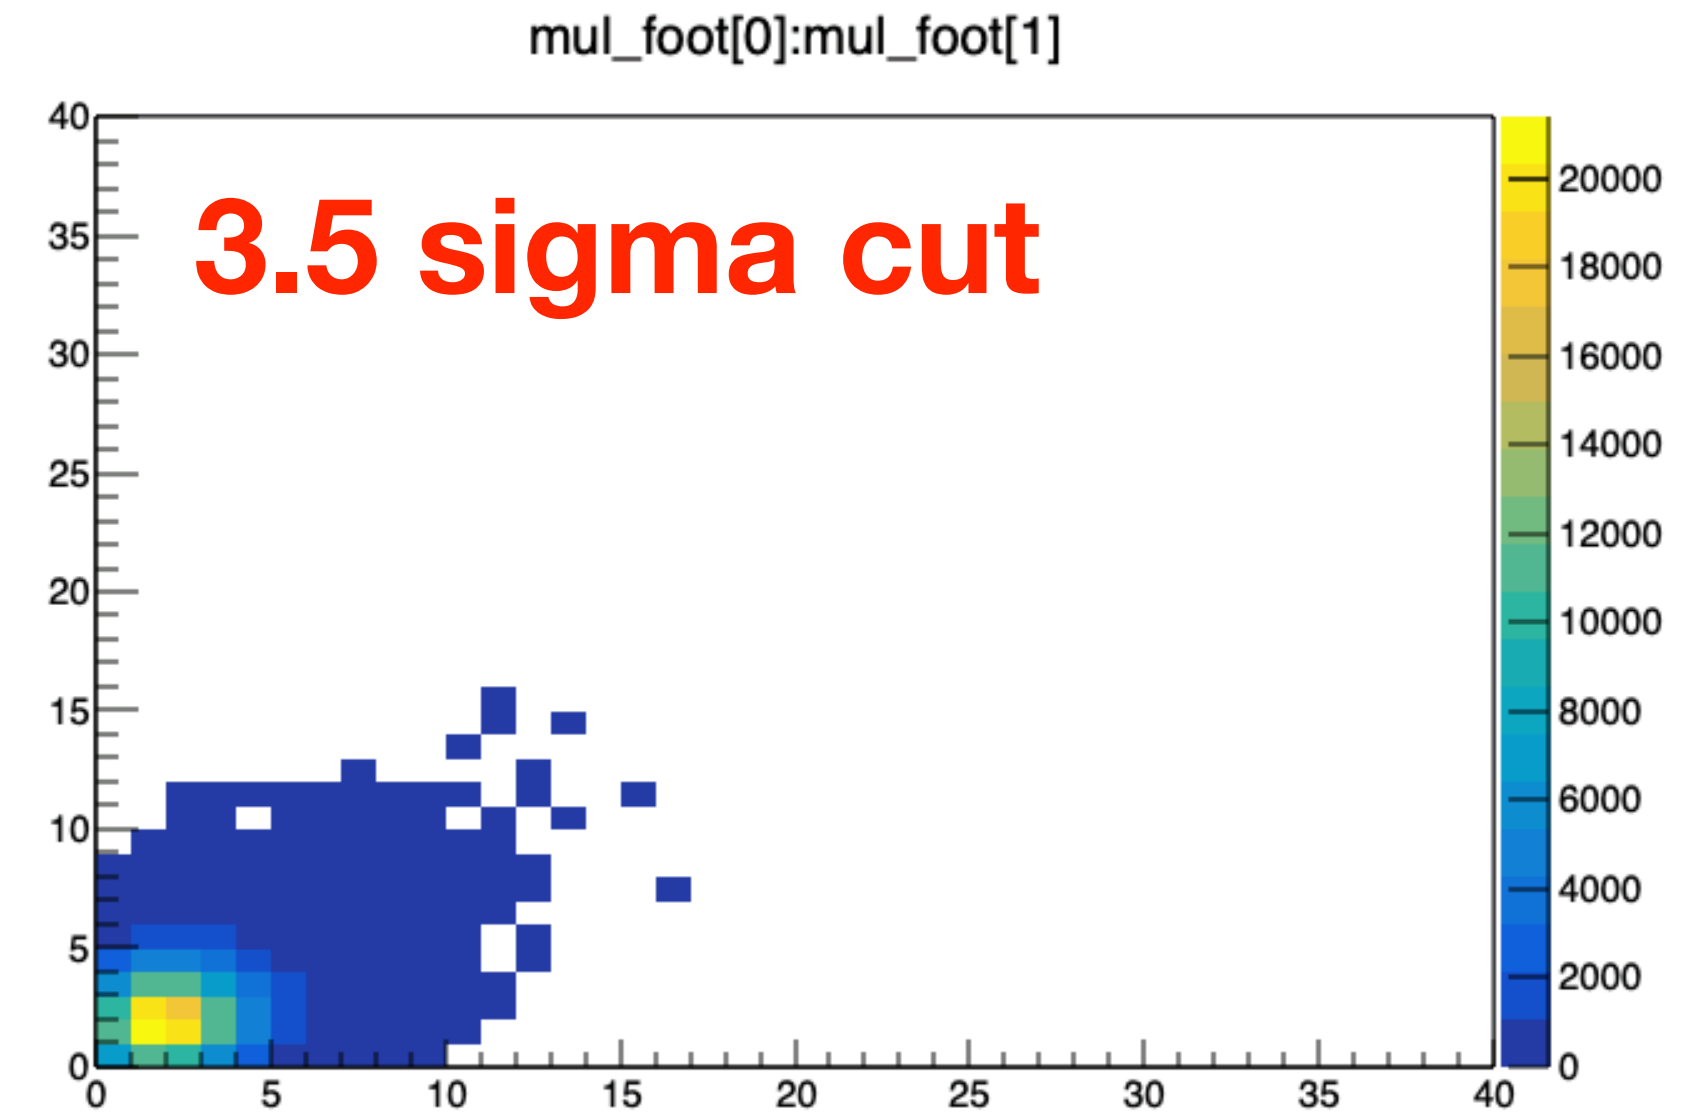

$$\epsilon = \frac{N_{2|1}}{N_1} \times 100\%$$

Method 1: 4 sigma (fine) threshold on  $N_1$  and  $N_{2|1}$

Method 2: fixed threshold on  $N_1$  (15 ADC)  
and variable threshold on  $N_{2|1}$

# 430 MeV protons

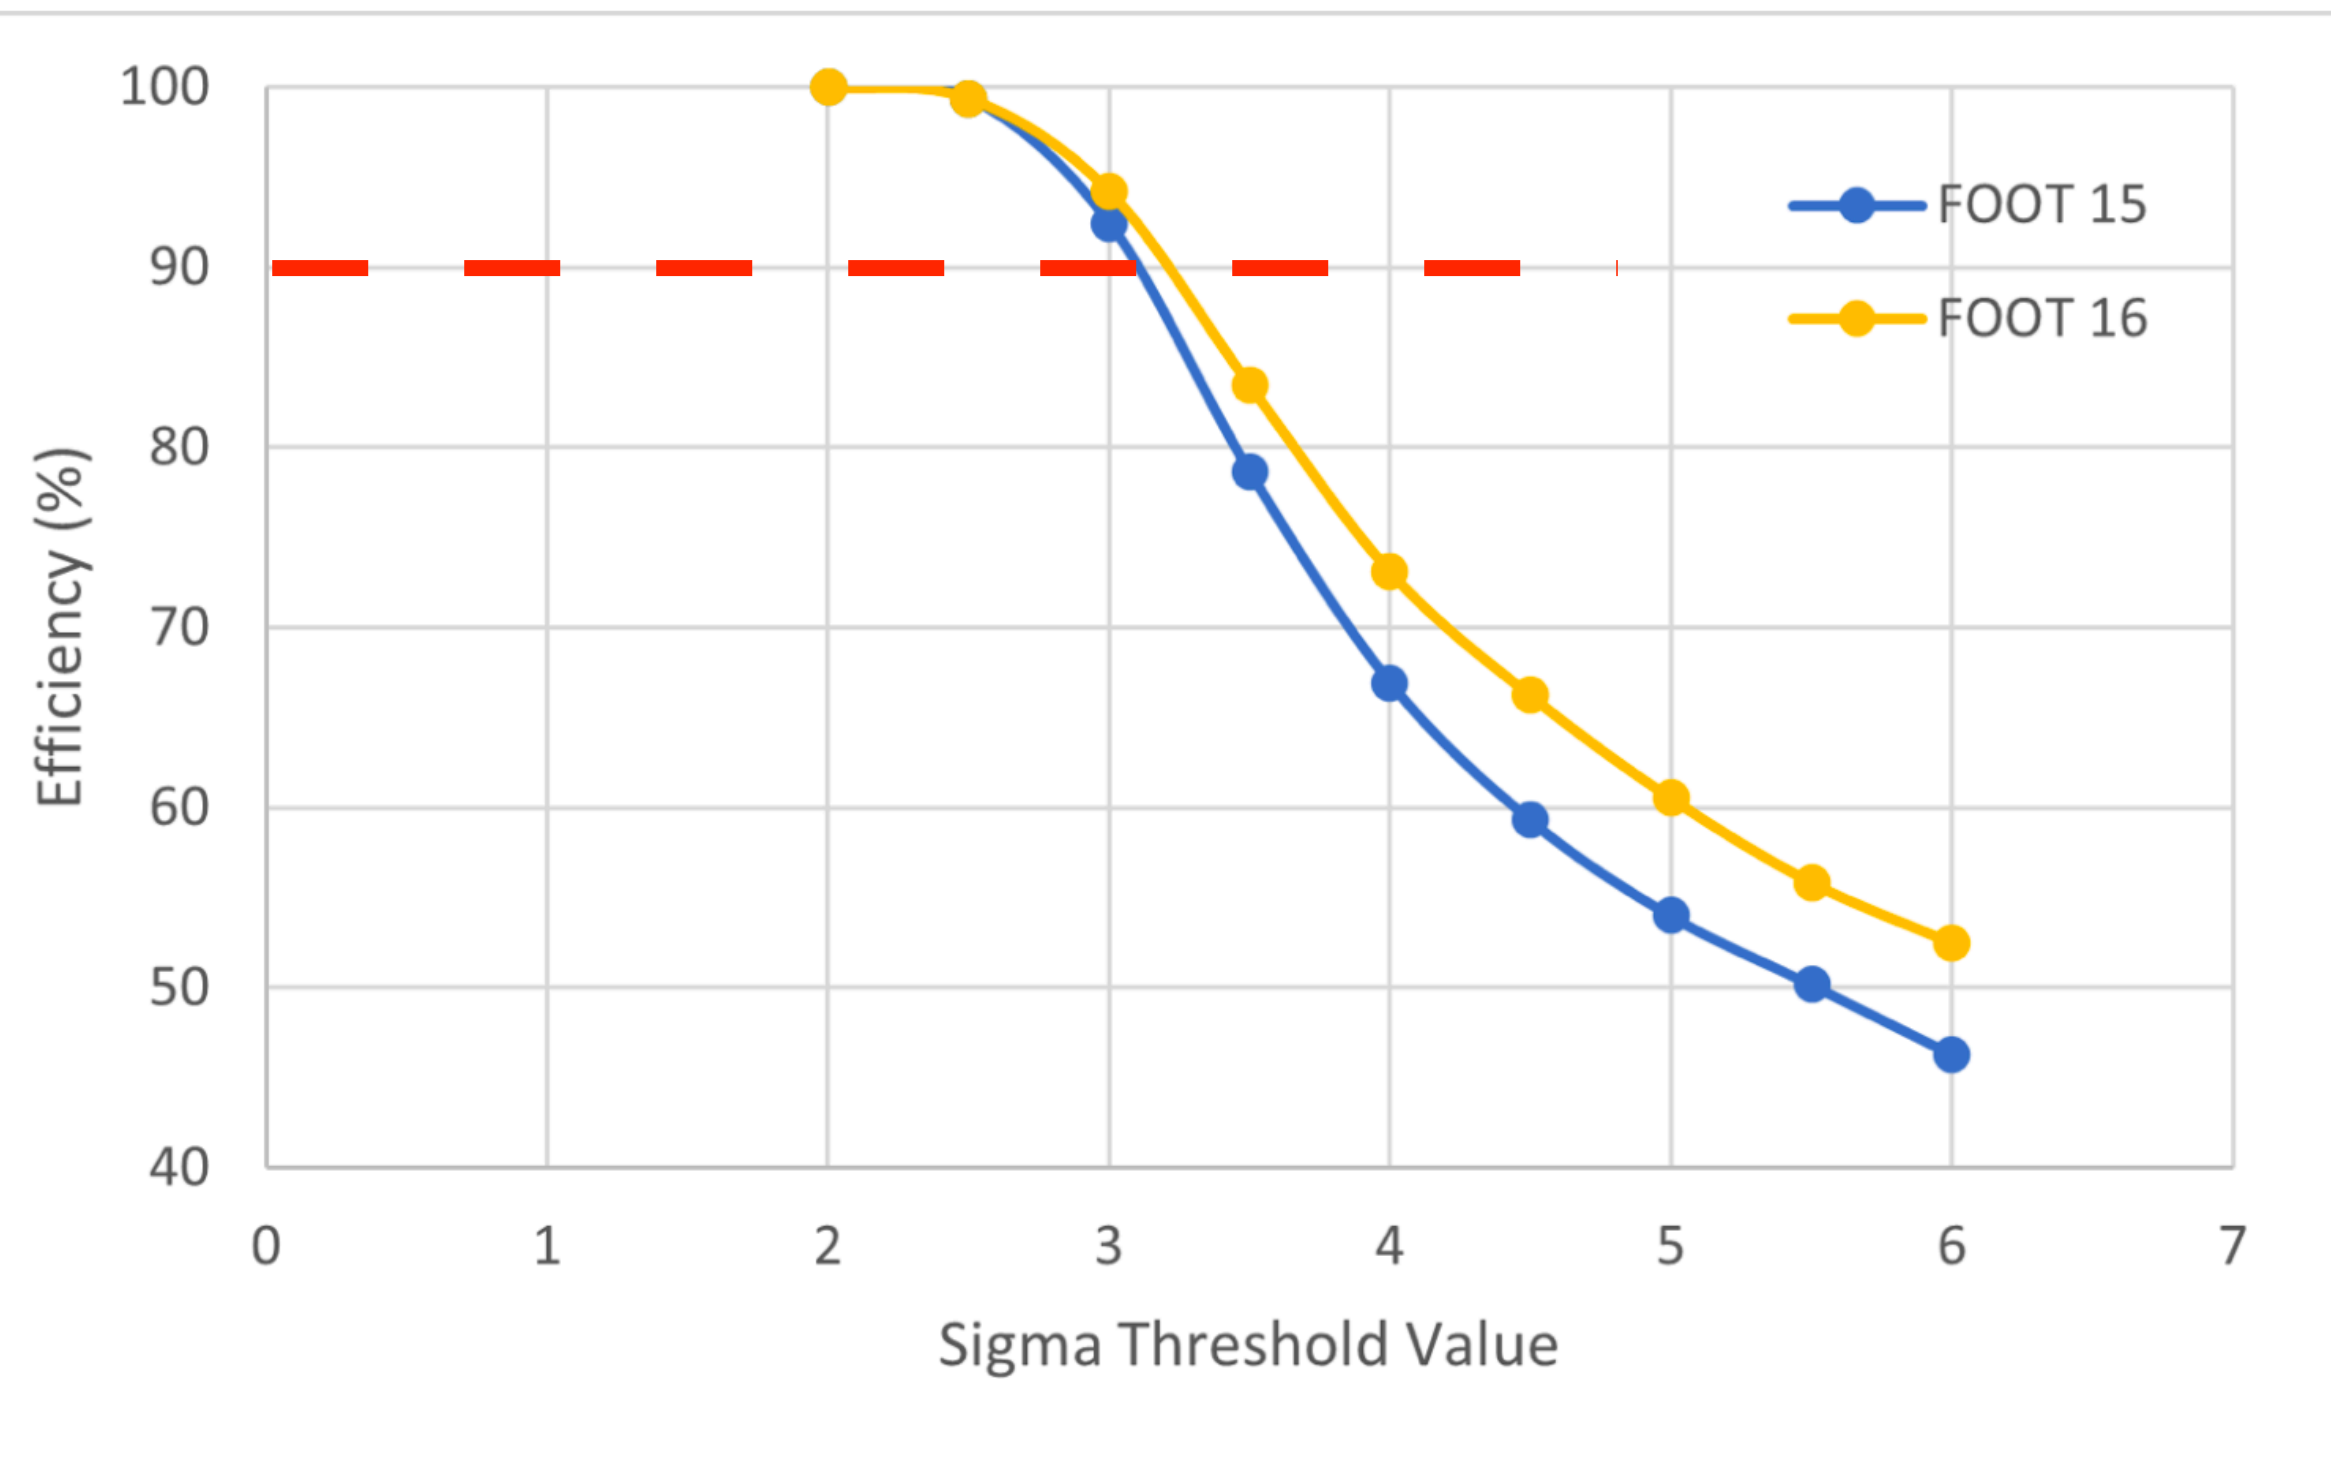

## Multiplicity of clusters per detector

# Method 2: beam centered on the detectors

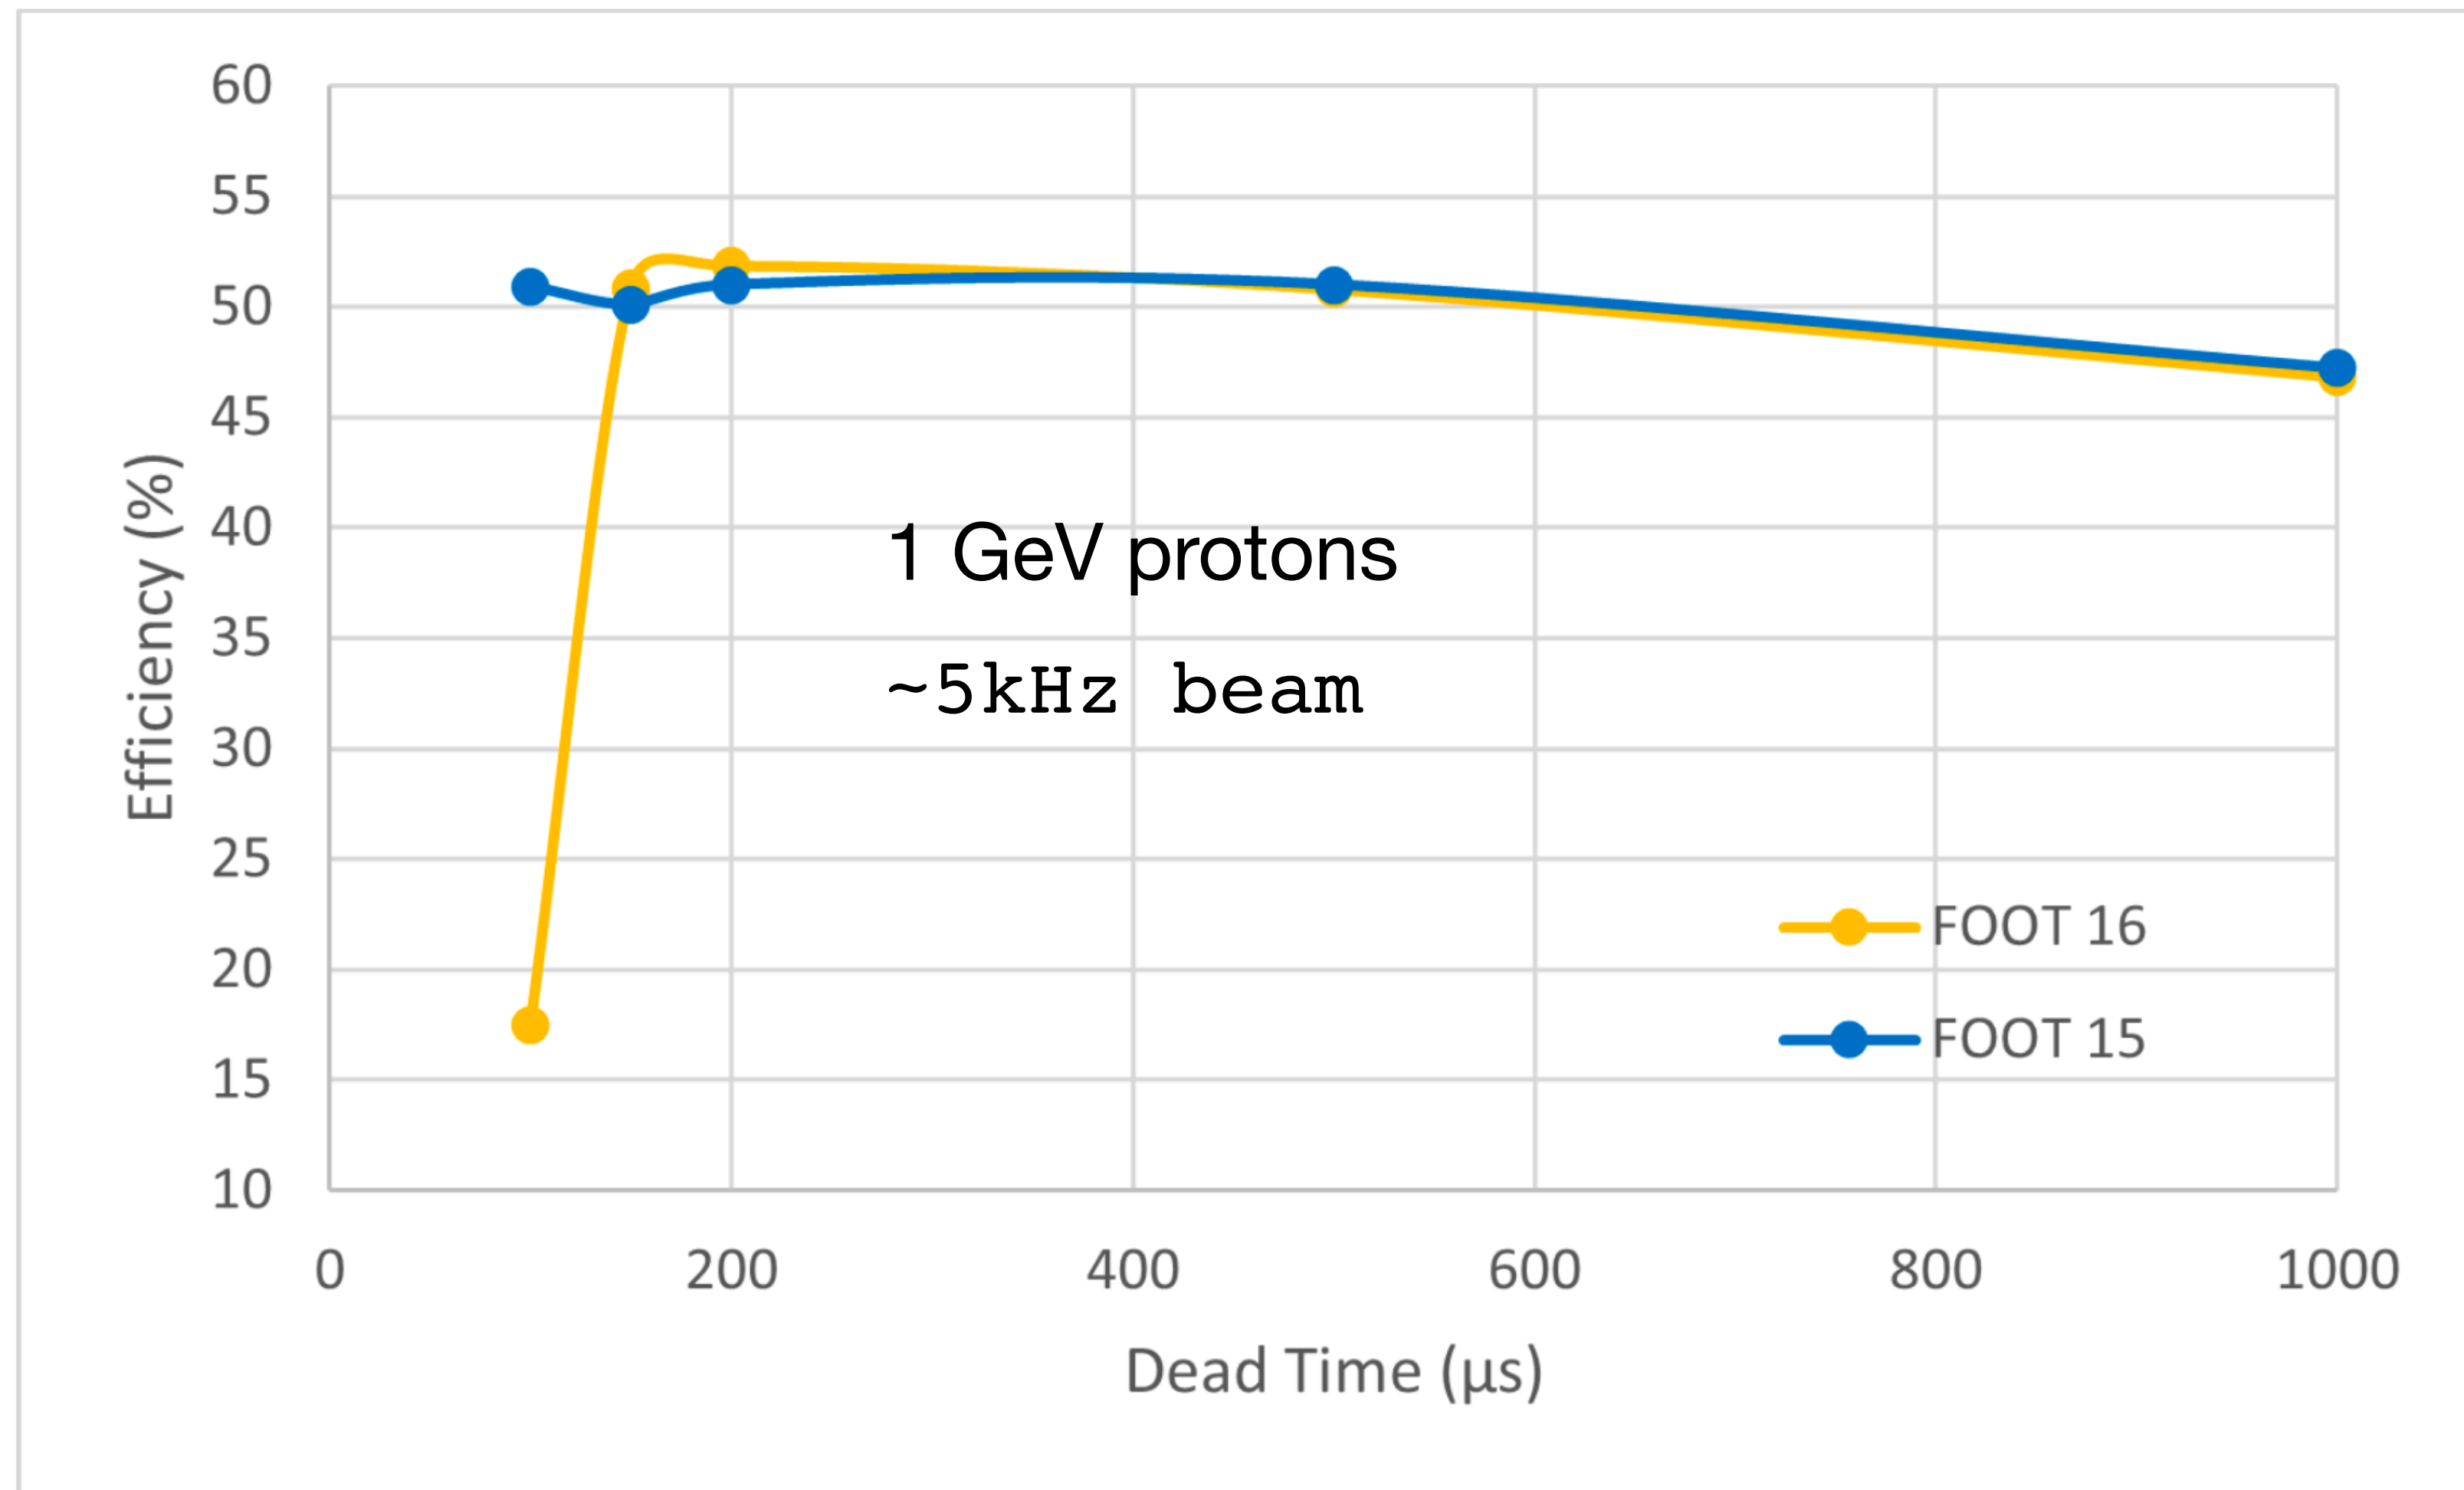

## 430 MeV protons

## 1 GeV protons

# Efficiency vs. deadtime setting (centered beam, method 1)

*That's all Folks!*
