

Everything you always wanted to know about CbmRoot

But were afraid to ask

Outline

- History
 - Already more than 20 years of CbmRoot
- Infrastructure behind CbmRoot development
 - Tools
- Workflow
 - How to get changes into CbmRoot
- Summary and Outlook

The Beginning

- During the early development phase there was no separation into FairRoot and CbmRoot
 - 2002 two meetings (1, 2) at GSI took place to discuss the possibility of an experiment which should study dense baryonic matter using the planned new accelerator
 - The [first CBM Collaboration Meeting](#) was in January 2003
- CBM needs simulations to prove that the planned experimental setup works for the physics they are after
- First implementation in Geant4

The Pregnancy

- In the first CBM collaboration meeting (Jan. 29, 2003) the future FairRoot is discussed
 - Exploration of Virtual Monte Carlo (VMC)
 - D. Bertini and M. Al-Turany (GSI)
 - Also D. Kresan and R. Karabowicz were present
 - All 4 are now working for GSI IT
- In the second CBM collaboration meeting (Jul. 7-8, 2003) the first presentation about the VMC based framework is given
 - The simulation tools VMC and Geant4 (D. Bertini, GSI)
 - Unfortunately the presentation is lost

The Birth

- During the third meeting (Feb. 11-13, 2004) the new simulation framework was presented the first time
 - [Status of the CBM simulation framework](#) (M. Al-Turany, GSI)
- The first official release was done only some days later at 10.03.2004 in a CVS repository
 - We can celebrate more than 20 years of CbmRoot and also FairRoot !!!!
- Development before was done in private repositories which are probably lost
- All developments since then are accessible from the different repositories
 - CVS repositories are not freely accessible

General requirements

- Software should be usable in short time due to deadlines for CBM (LOI, TDRs, ...)
 - Only two developers
 - Impossible to write everything from scratch
- Easy to use
 - Users are physicists and not experienced developers
- Easy to maintain
 - Reuse existing tools and developments
 - Keep the code base as small as possible
- Easy to install
 - Don't depend on a specific OS or compiler

Motivation

- CBM needs a reliable simulation environment in short time (deadlines for LOI, TDR, ...)
- Limited manpower (two developers)
- Reuse as much as possible existing code and tools
- Profit from development done for other experiments
 - ALICE: VMC, Eve
 - Hades: ASCII geometry interface, parameter management
- Which MC transport simulation to use
 - One would like to use the modern and maintained [GEANT4](#)
 - lack of knowledge about GEANT4 (intrinsic cuts / physics list ...)
 - **At that time it was** extremely difficult to get support for working with Geant4
 - Better knowledge of “old” MC’s: [GEANT3](#), [FLUKA](#)

Design Decisions I

- Immediate code release
 - Get feedback and bug fixes very fast
- Modular code
 - Allow to change algorithms and detector description easily
- Keep the code base minimal
 - Only implement what is really needed and not what potentially could be used in 20 years
- Reuse existing standard tools if they do the job
 - Build system
 - Code documentation
 - Code management

Design Decisions II

- Performance and stability has highest priority
 - Avoid fights about idealistic views and design concepts
 - Use C-Arrays where appropriate
 - Use TClonesArray for data instead of STL containers
 - Speed
 - Serialization of data to file
- Reuse existing code and concepts
 - Basic ideas and structures from AliRoot
 - Geometry and parameter interfaces from Hades
 - Virtual Monte Carlo for simulation
 - ROOT geometry package for navigation
 - Extent ROOT TTask for reconstruction and analysis

Main features I

- Using VMC for the simulation allows
 - Running different transport MCs from the same application
 - No need to change any user code (detector response, IO, physics settings) for a specific transport model
 - Describe the geometry only once and use it for any transport MC
 - Convert it to native geometries of the transport engine if needed/wanted
 - Allows to use the navigation from ROOT or the transport engine
- Dynamic event structure
 - Detectors can be added/replaced/removed without changing the code
 - Simple analysis can be done in ROOT without loading additional libs
 - Transient (in memory) and persistent (on file) objects are the same
 - ROOTs TTree friend mechanism allows to connect information of different files without copying and data from file to file

Main features II

- Don't create a binary
 - Use the ROOT binary and ROOTs plug-int mechanism to dynamically load libraries when needed
 - Meanwhile there are also some binaries, mainly for online
- Don't use a fixed setup or run configuration
 - Use ROOT macros to define the experimental setup or the list of tasks for a reconstruction or analysis
 - Also use ROOT macros read at runtime to set Geant3 or Geant4 configurations
- These two features enables the user to switch very flexible between experimental setups and configurations
 - Change macro and rerun

Interlude: Monte Carlo Simulation

- Monte Carlo (MC) simulations are a mathematical method to approximate the possible results of an uncertain event
- MC simulations are used to model the probability of different outcomes in a process that cannot easily be predicted due to the intervention of random variables
- A MC simulation consist of the following three steps
 - Modelling: Create a model which describes the random variables and their connection
 - Simulation: Do many iterations of the simulation by exchanging the random variables by random numbers
 - Analysis: Analyse the results of the simulation to extract the probability of different results

Interlude: Monte Carlo Simulation Examples

- Throwing a dice
 - Result can be any of the numbers 1-6 → Random variable
 - Model the dice
 - Draw a random number between 1-6
 - Result can be any of the numbers 1-6
 - Redo the simulation many times and plot the results
 - Probability for any of the numbers will be ~1/6

- Calculate π
 - The size of the circle to the size of the box is like the number of random points inside the Circle to the total number of points

$$\frac{\text{Area}(\text{Circle})}{\text{Area}(\text{Box})} = \frac{\pi \cdot r^2}{(2 \cdot r)^2} = \frac{\pi}{4} \Rightarrow \pi = \frac{4 \cdot \text{Points}(\text{Circle})}{\text{Points}(\text{Total})}$$

Interlude: Monte Carlo Transport Simulations

- Simulation software designed to describe the passage of elementary particles through matter, using MC methods
- Create a model of the experimental geometry and the physics processes
- Simulate the passage of many particles through the geometry
- Analyse the intersections of the particle trajectories with the active parts of the detector geometry

Interlude: MC Transport in Detail I

Gold Target

Particle

- Build model of geometry and physics
- Put one particle at position (x, y, z) with momentum (P_x, P_y, P_z)
- Calculate the distance to the next boundary in direction of particle track
- Calculate the distance where the next interaction in the current medium happens
- Depending on the medium, the particle and the physical settings there are several physical processes to be taken into account

Interlude: MC Transport in Detail II

Gold Target

Silicon detector

- Particle has no physics interaction till the next boundary
- Transport simulation moves particle to the next boundary

Interlude: MC Transport in Detail III

- Particle has no physics interaction till the next boundary
- Transport simulation moves particle to the next boundary (target)
- Due to problems with mathematical precision the particle is moved slightly inside the new volume
- In the target again the distance to the next boundary and to any physics interaction is checked
- If an interaction in the target happens the particle is moved to the position of the interaction and the particle properties are updated
 - Scattering changes the momentum and such the direction of the particle
- Repeat two previous steps till the particle leaves the volume

Interlude: MC Transport in Detail IV

Gold Target

Silicon detector

- Particle has no physics interaction till the next boundary
- Transport simulation moves particle to the next boundary (silicon detector)
- Since the detector is an sensitive part of the detector some user code is called for every step in the sensitive volume
- Allows to access detailed information about the particle like
 - Position
 - Momentum
 - Energy
 - Energy Loss
 - Particle ID
 - ...

Interlude: MC Transport in Detail IV

Gold Target

Silicon detector

- Particle has no physics interaction till the next boundary
- Transport simulation moves particle to the next boundary (silicon detector)
- Since the detector is an sensitive part of the detector some user code is called for every step in the sensitive volume
- Allows to access detailed information about the particle like
 - Position
 - Momentum
 - Energy
 - Energy Loss
 - Particle ID
 - ...
- Follow the particle until it is stopped, it disappears or it crosses the boundary of the experiment

Interlude: Virtual Monte Carlo

- Virtual Monte Carlo is a software framework that enables the simulation of different MC transport simulations without modifying the user code
- Decouples the user code from the concrete MC transport simulation
- Allows to use different MC transport simulations
- Currently the following three are supported by VMC
 - Geant3 (Fortran, 1982-2000)
 - Geant4 (C++, 1998-2024)
 - Fluka (Fortran, ?-2024)
- Geant: **G**eometry **a**nd **T**ransport
- Fluka could not be used to licensing issues

Infrastructure

- Build system
 - Makefiles v1: 10.03.2004 – 16.07.2004
 - Makefiles v2: 16.07.2004 – 23.06.2005
 - Autotools: 23.06.2005 – 27.01.2009
 - CMake: 23.11.2006 - today
- C++ standards
 - C++98 till 2012
 - C++11 2012 – 2018
 - C++17 2018 – today

Repositories

- Repositories
 - 3 different CVS repos
 - cbm_vmc: 10.03.2004 – 16.07.2004
 - cbmroot: 16.07.2004 – 23.06.2005
 - cbmroot2: 23.06.2005 – 14.09.2006
 - SVN repository
 - fairroot: 14.09.2006 – 02.06.2020
 - Repository was restructured several times
 - Repository includes also the code of FairRoot and other experiments
 - GIT repository
 - CbmRoot: 03.06.2020 – today

- CMake is an open source meta build system
- CMake generates native build environment
 - Makefiles
 - IDE project files
 - ...
- CMake is a set of tools
 - cmake – build environment generator
 - ctest – tool for automatic testing
 - cpack – packaging tool
 - ccmake – graphical frontend to cmake
- CMake is operating system and compiler independent

- CMake is controlled by creating CMakeLists.txt files in each directory which belongs to a project
- CMake creates a very accurate dependency tree
 - A rerun of the build process compiles only files which have changed and all their dependencies. All other files are not recompiled
- Most of our CMakeLists.txt only define variables and finally call one command
 - Example on the next slides
- Developer normally needs to add new files to a variable
 - For anything else or in case of problems please contact the software team

Example CMakeLists.txt

```
set(INCLUDE_DIRECTORIES
  ${CMAKE_CURRENT_SOURCE_DIR}
)
```

```
set(SRCS
  CbmFieldConst.cxx
  CbmFieldContFact.cxx
  CbmFieldMap.cxx
  CbmFieldMapCreator.cxx
  CbmFieldMapData.cxx
  CbmFieldMapSym2.cxx
  CbmFieldMapSym3.cxx
  CbmFieldPar.cxx
  CbmBsField.cxx
  CbmFieldCreator.cxx
  CbmFieldMapDistorted.cxx
  CbmFieldMapSym1.cxx
)
```

**Directories with
needed headers**

```
set(LIBRARY_NAME CbmField)
set(LINKDEF ${LIBRARY_NAME}LinkDef.h)
set(PUBLIC_DEPENDENCIES
  FairRoot::Base
  FairRoot::ParBase
  ROOT::Core
)
```

```
set(PRIVATE_DEPENDENCIES
  ROOT::MathCore
  ROOT::RIO
  ROOT::Hist
  ${VMCLIB}
)
```

```
generate_cbm_library()
```

Example CMakeLists.txt

```
set(INCLUDE_DIRECTORIES
  ${CMAKE_CURRENT_SOURCE_DIR}
)
```

```

generate_cbm_library()
```

Example CMakeLists.txt

```
set(INCLUDE_DIRECTORIES
  ${CMAKE_CURRENT_SOURCE_DIR}
)
```

```
set(SRCS
  CbmFieldConst.cxx
  CbmFieldContFact.cxx
  CbmFieldMap.cxx
  CbmFieldMapCreator.cxx
  CbmFieldMapData.cxx
  CbmFieldMapSym2.cxx
  CbmFieldMapSym3.cxx
  CbmFieldPar.cxx
  CbmBsField.cxx
  CbmFieldCreator.cxx
  CbmFieldMapDistorted.cxx
  CbmFieldMapSym1.cxx
)
```

**Library dependencies
target not lib names
Private: only used in
source file
Public: used in headers**

Two black arrows originate from the text block. One arrow points to the 'PUBLIC_DEPENDENCIES' list, and the other points to the 'PRIVATE_DEPENDENCIES' list.

```
set(LIBRARY_NAME CbmField)
set(LINKDEF ${LIBRARY_NAME}LinkDef.h)
set(PUBLIC_DEPENDENCIES
  FairRoot::Base
  FairRoot::ParBase
  ROOT::Core
)
```

```
set(PRIVATE_DEPENDENCIES
  ROOT::MathCore
  ROOT::RIO
  ROOT::Hist
  ${VMCLIB}
)
```

```
generate_cbm_library()
```

Example CMakeLists.txt

```
set(INCLUDE_DIRECTORIES
  ${CMAKE_CURRENT_SOURCE_DIR}
)
```

```
set(SRCS
  CbmFieldConst.cxx
  CbmFieldContFact.cxx
  CbmFieldMap.cxx
  CbmFieldMapCreator.cxx
  CbmFieldMapData.cxx
  CbmFieldMapSym2.cxx
  CbmFieldMapSym3.cxx
  CbmFieldPar.cxx
  CbmBsField.cxx
  CbmFieldCreator.cxx
  CbmFieldMapDistorted.cxx
  CbmFieldMapSym1.cxx
)
```

```
set(LIBRARY_NAME CbmField)
set(LINKDEF ${LIBRARY_NAME}LinkDef.h)
set(PUBLIC_DEPENDENCIES
  FairRoot::Base
  FairRoot::ParBase
  ROOT::Core
)
```

```
set(PRIVATE_DEPENDENCIES
  ROOT::MathCore
  ROOT::RIO
  ROOT::Hist
  ${VMCLIB}
)
```

```
generate_cbm_library()
```

Here the magic happens

Example CMakeLists.txt

```
set(INCLUDE_DIRECTORIES  
  ${CMAKE_CURRENT_SOURCE_DIR}  
)
```

Library name
Linkdef file name

```
set(LIBRARY_NAME CbmField)  
set(LINKDEF ${LIBRARY_NAME}LinkDef.h)  
set(PUBLIC_DEPENDENCIES  
  FairRoot::Base  
  FairRoot::ParBase  
  ROOT::Core  
)
```

```
set(SRCS  
  CbmFieldConst.cxx  
  CbmFieldContFact.cxx  
  CbmFieldMap.cxx  
  CbmFieldMapCreator.cxx  
  CbmFieldMapData.cxx  
  CbmFieldMapSym2.cxx  
  CbmFieldMapSym3.cxx  
  CbmFieldPar.cxx  
  CbmBsField.cxx  
  CbmFieldCreator.cxx  
  CbmFieldMapDistorted.cxx  
  CbmFieldMapSym1.cxx  
)
```

**Directories with
needed headers**

**Library dependencies
target not lib names**
**Private: only used in
source file**
Public: used in headers

```
set(PRIVATE_DEPENDENCIES  
  ROOT::MathCore  
  ROOT::RIO  
  ROOT::Hist  
  ${VMCLIB}  
)
```

```
generate_cbm_library()
```

List of source files

**Here the magic
happens**

- Ideal integration with CMake
- Easy to setup new tests
- A test can be anything which is executable
 - Scripts (shell, perl ..)
 - Executable
 - Root macros
- Help to automatically identify problems when they occur
- Direct feedback for developers when they play with new features
- CTest is used for our CI infrastructure

- Tests are defined also in CMakeLists.txt files
- Find many examples in macro directory
- Executing a ROOT macro is as easy as shown in macro/field/CMakeListst.txt
 - Generate shell script to setup the runtime environment and execute the ROOT macro
 - Adds the tests to the list of existing tests
 - Set test properties (max. runtime, and successful string)

```
GENERATE_ROOT_TEST_SCRIPT(${CBMROOT_SOURCE_DIR}/macro/field/FieldMapTest.C)
```

```
add_test(field_field ${CBMROOT_BINARY_DIR}/macro/field/FieldMapTest.sh)
```

```
SET_TESTS_PROPERTIES(field_field PROPERTIES TIMEOUT "60")
```

```
SET_TESTS_PROPERTIES(field_field PROPERTIES PASS_REGULAR_EXPRESSION "Test Passed;All  
ok")
```

- How to get new files or file changes into the code base of a project?
- Typical project use cases
 - Single developer
 - Can do whatever he wants
 - Small number of developers
 - Only few or many changes
 - Developers working on same or different code parts
 - Probably coordination needed to avoid interference
 - Large number of developers
 - Very likely the developers will interfere with each other
 - Without coordination the development becomes impossible

- How to coordinate your work?
 - Everybody can add/change files in a common workplace
 - Developers can only add/change files in subparts of the workplace
 - Only single person can add/change files
 - Send changes using mail
 - Let him copy your code (if possible)
 - Use source code management
 - Several tools available (CVS, SVN, git, ...)
 - Some of them already define a workflow
 - Has several advantages
- Define a workflow as early as possible
- Use the workflow

- Over the years we used several workflows
 - Depending on the source code management system
 - Beginning: everybody could do everything
 - Intermediate: developer had permissions on directory/file level
 - Now: again everybody can do everything **BUT**
 - changes are reviewed automatically
 - If automatic review was successful another developer reviews the changes
 - Only if both steps were successful the changes are added to the code base

Source Code Management

Underlying problem

- How do you keep track of changes made to your files?

- Do the bookkeeping yourself.

Create new files every time you do a change.

- Will create a huge number of files which are complicated to organize
- May blow up your disk space

- No metadata information if not saved separately

- How do you communicate changes to your collaborators?

- Send changes by mail?
- Work all in the same account?

- Use a system which hides all the complications from the user

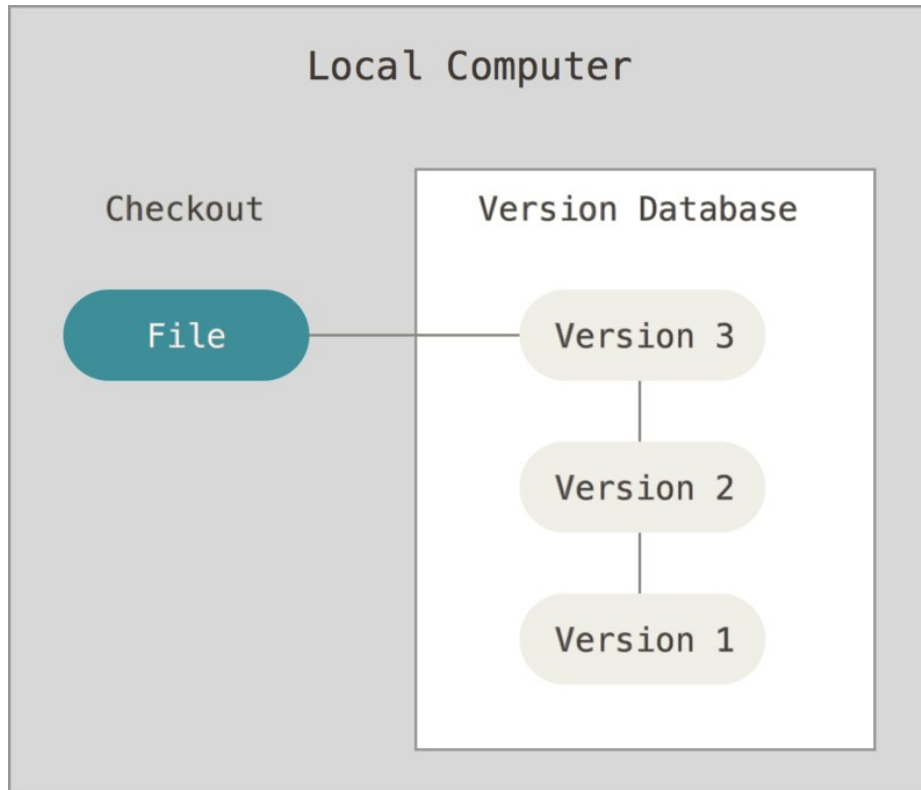

- A version control system (VCS) manages documents over time
 - A VCS keeps the history of all changes
 - Many versions of every file
 - Allows to go back to an older version of the file
 - Show differences between different versions
 - Log messages name the reason for changes
 - ...
- A VCS coordinates the work of multiple authors
 - Avoid conflicts between the developments of different developers
- A VCS allows user authentication and controlled access to files
 - Read/Write permissions for user and groups to files and directories

Which information is stored?

Content	what has changed?
Date	when did it change?
Author	who changed it?
Reason	why has it changed?

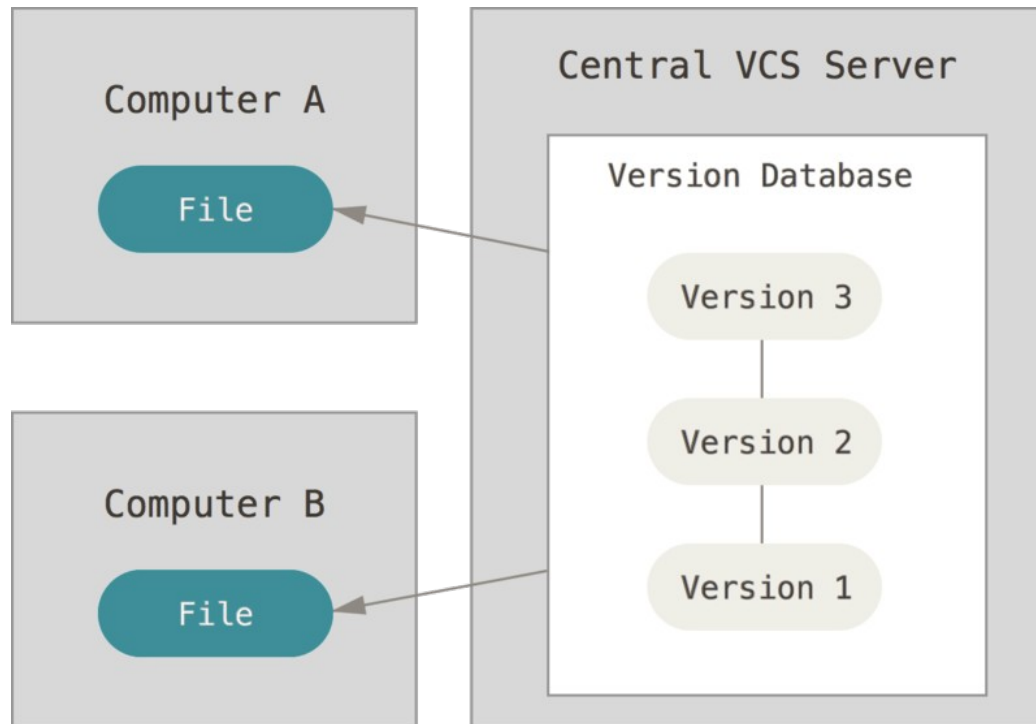

} VCS does this
} you enter this

- The Reason should be meaningful and explanatory !!
- Don't say how you have changed but why and what
 - **Bad:** bug-fix
 - **Good:** Correctly init variable x because of division by zero
- Separate subject from body with a blank line
- Limit the subject line to 50 characters
- Wrap the body at 72 characters

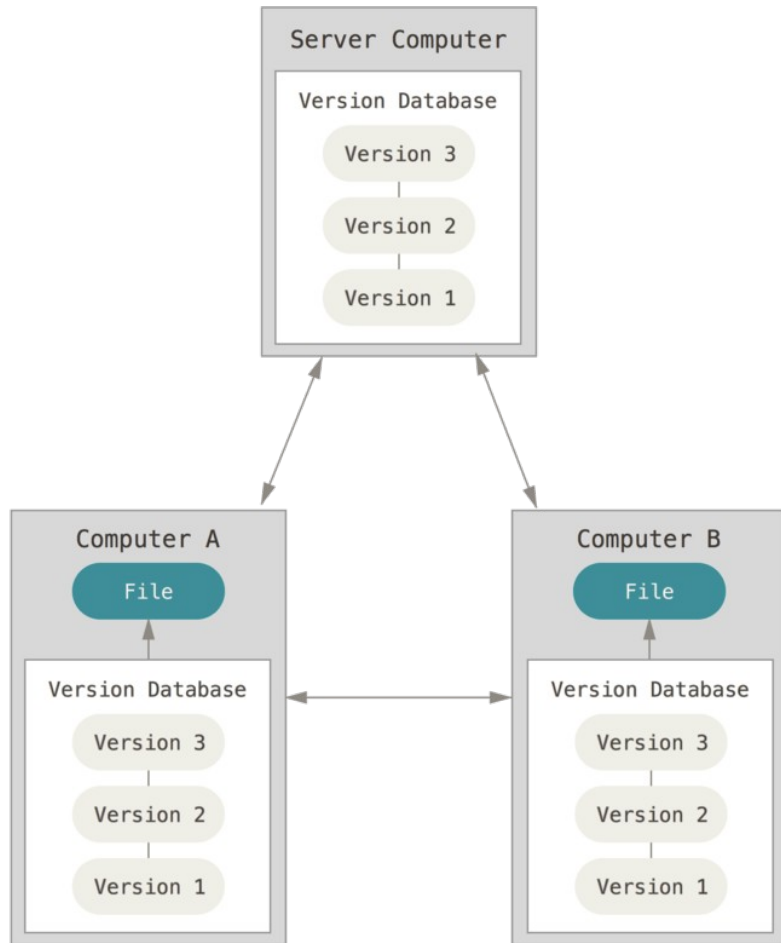

- Store differences between versions (deltas) for each file in a special format
- Less error prone than manually managing file versions
- E.g. RCS

Central Version Control System

- Allows a collaboration of different developers
- Fine grained access control is possible
- Central Server is a single point of failure
- Commits went always to the central server
- If the server is locally on your computer it works as local VCS
- E.g. CVS or Subversion

- Commits are done first locally which allows to save the full history of changes locally
 - Each computer has a copy of the full history
 - No single point of failure since every client copy is a full backup
- Depending on workflow synchronization can be complicated
 - Most workflows use a central server
- E.g. Git, Mercurial

- Local and central version control systems define a more or less fixed workflow
- With a distributed version control system many different workflows become possible
- Git is a very powerful toolbox to implement many different workflows
 - Good: very powerful and flexible
 - Bad: very powerful and flexible
- For CbmRoot we chose to use GitLab as repository
 - A software repository, or repo for short, is a storage location for software packages (Wikipedia)

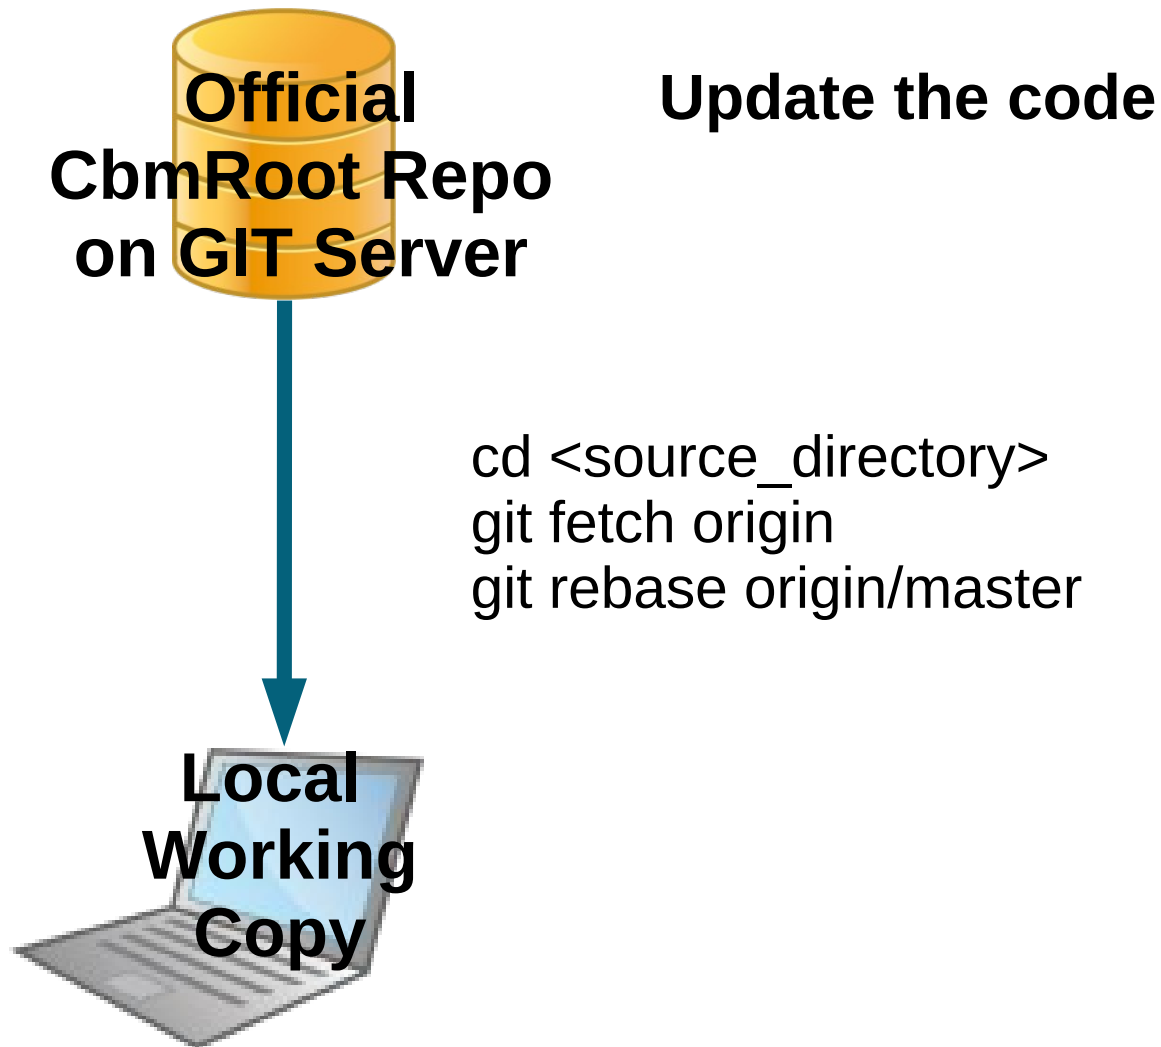

- The “Central Repository” is the official source of the project on a central server
 - GitHub or GitLab are well known repository providers
 - Allow to implement workflows
 - **Everything else isn't an official version !!!**
- A “Fork” is a private clone (copy) of the official repository on the central server at a given point in time
 - Done using the services provided by GitHub or GitLab
 - Allow to do changes without affecting the central repository
 - Not synchronized automatically with official repository
 - Needed to integrate changes into the “Central Repository”
- The “local repository” or “working copy” is a clone from the central server on your local computer

- User
 - Person who only intends to download and use the CbmRoot source code
- Developer
 - Person who intends to get code into the official CbmRoot repository
- Manager
 - Person who manages the official CbmRoot repository
 - 5-6 dedicated people
 - https://git.cbm.gsi.de/computing/cbmroot/-/project_members
 - This workflow is not covered here

Get the code initially

```
git clone https://git.cbm.gsi.de/computing/cbmroot
```

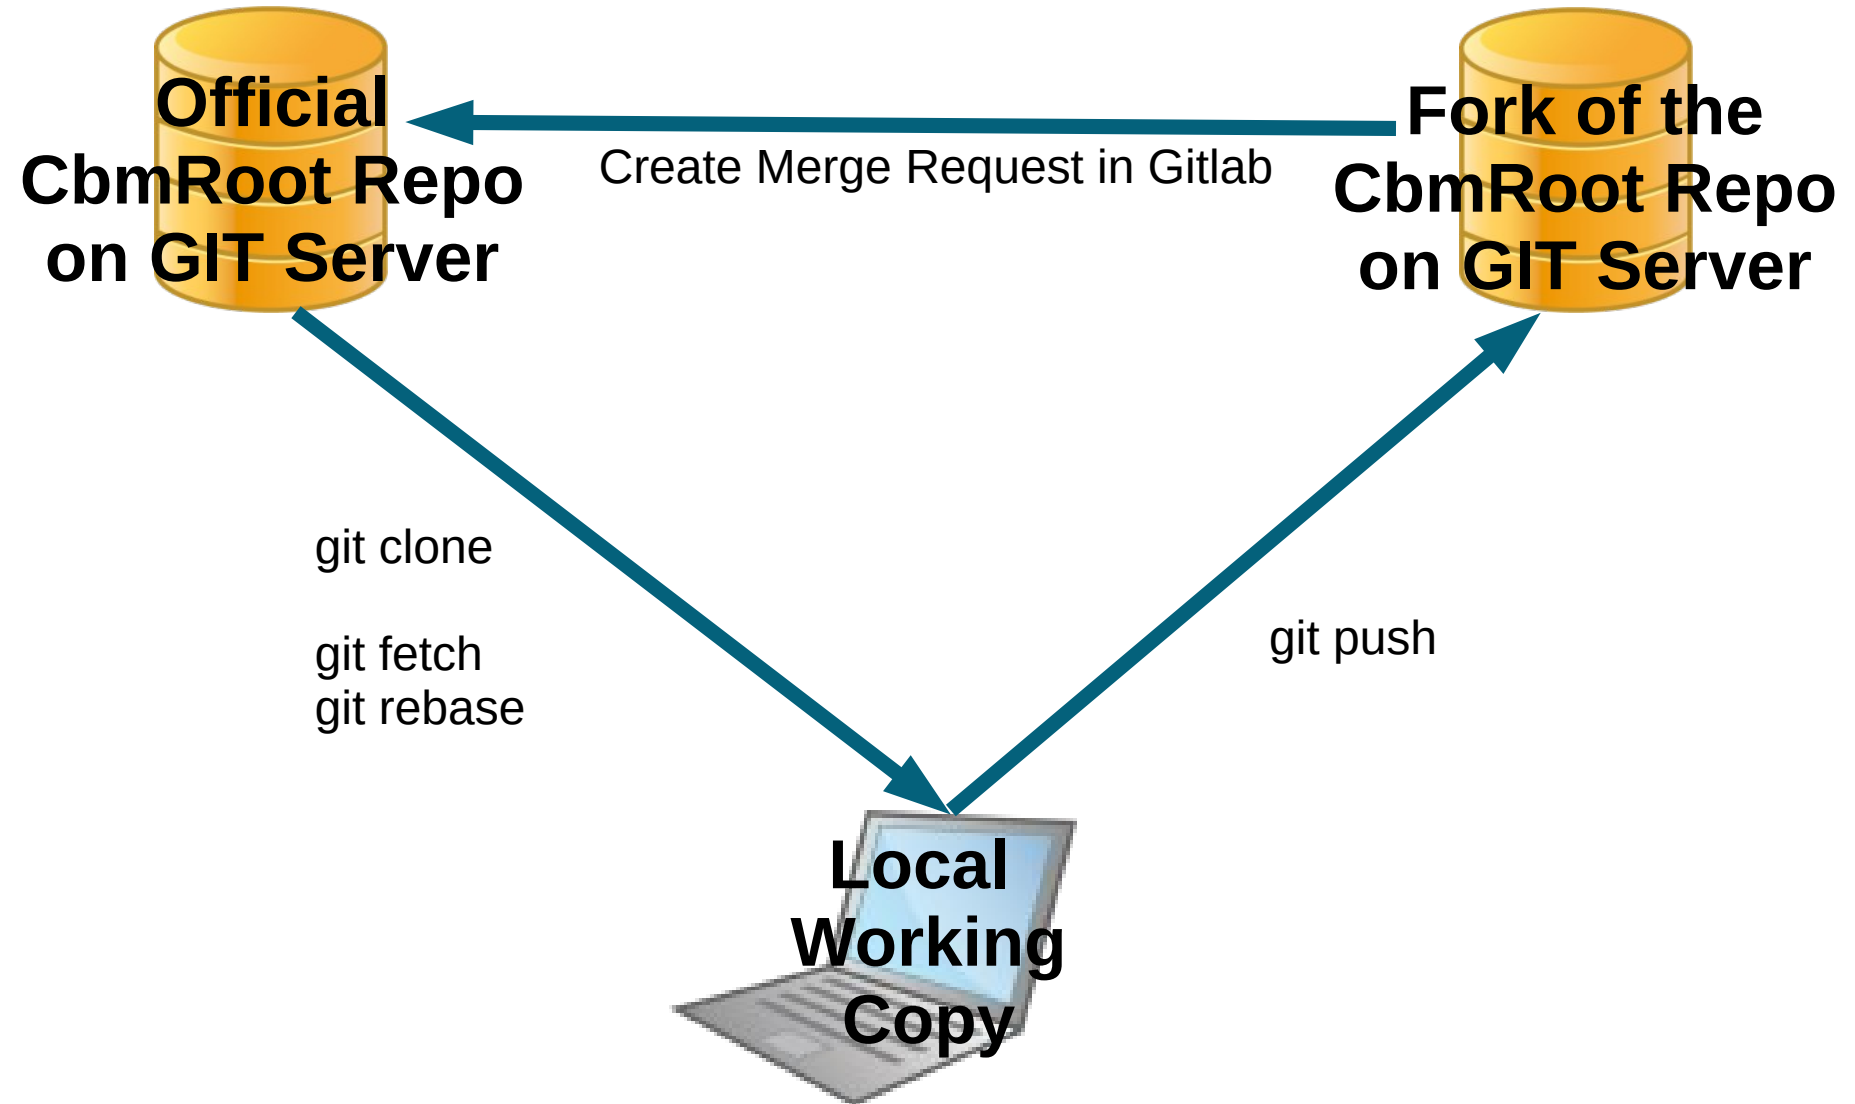

- Very simple workflow
- Either get the code initially or update your local working copy to the latest state

- Developers get the code in the same way as the users
- Developers get updates in the same way as the users
- Nobody is allowed to upload (push) changes to the “Official directory”
 - This is even not allowed for administrators !!
- How do a developer get his local changes back into the “Official Repository”?
 - If the direct way is blocked we have to use a bypass
 - The following slides only cover this „Merge Request“ workflow

- The developer offers his code and asks for adding it
 - Like sending a mail with patches to the main developer asking him to add them to the official code
- Workflow is completely implemented in GitLab
 - Most steps are automatic
 - Relevant people are informed via mails
 - Allow extensive testing and peer review before adding code
- Advantages for Maintainers
 - Reduce workload enormously
 - Problems are mostly found before adding the code
 - In case of problems the developer has to fix them

Workflow for developers

Final Picture

- Have you seen this workflow already?
- Have you used the workflow before?
- The workflow is described in the following presentation
 - [CbmRoot Merge Request Workflow](#)

- GitLab creates a new invisible branch in the main repository
 - The branch is deleted after the code is merged
 - Get the code in the local repository
 - `git fetch <repo_name> merge-requests/<id>/head:<local_branch_name>`
 - e.g. `git fetch upstream merge-requests/1879/head:mr-upstream-1879`
- GitLab starts the Continuous Integration
 - All stages and tasks of the CI are defined the file `.gitlab-ci.yml`
 - GitLab does only the orchestration, the actual work is done on a dedicated CI infrastructure
 - If the full CI chain was successful the Merge Request is marked to be merged
 - GitLab send mails to the Code Owners to inform them about the MR

- GitLab start jobs on the CI infrastructure as defined in the CI configuration
 - Jobs in stages can run in parallel
 - The stages run sequentially
- GitLab runners on the CI build nodes wait for work
 - Pull jobs from GitLab server
 - One runner can execute several executors
- Different Executors runners for different tasks
 - Docker Executor to do work inside docker containers
 - Apptainer Executor to build and test CbmRoot with the GSI specific VAEs (Debian 10, Debian 11 and CentOS 7)
 - Shell Executor to build and test CBmRoot on macosx

- Define Test Stages

- Once at the beginning of the config
- Several jobs per Stage possible

stages:

- checkRepository
- checkFormat
- build
- package
- verify
- finalise
- documentation

- Define job specifics

Job name

Stage

Executor (here running an Alpine Linux
inside a docker container)

When: MR to master branch of
computing/cbmroot repo

RebaseCheck:

stage: checkRepository

variables:

GIT_DEPTH: 200

image: alpine

tags:

- docker

only:

refs:

- merge_requests

variables:

- \$CI_MERGE_REQUEST_PROJECT_PATH == "computing/cbmroot" && \$CI_MERGE_REQUEST_TARGET_BRANCH_NAME == "master"

- Code
 - Executable or script
 - Need to return 0 on success

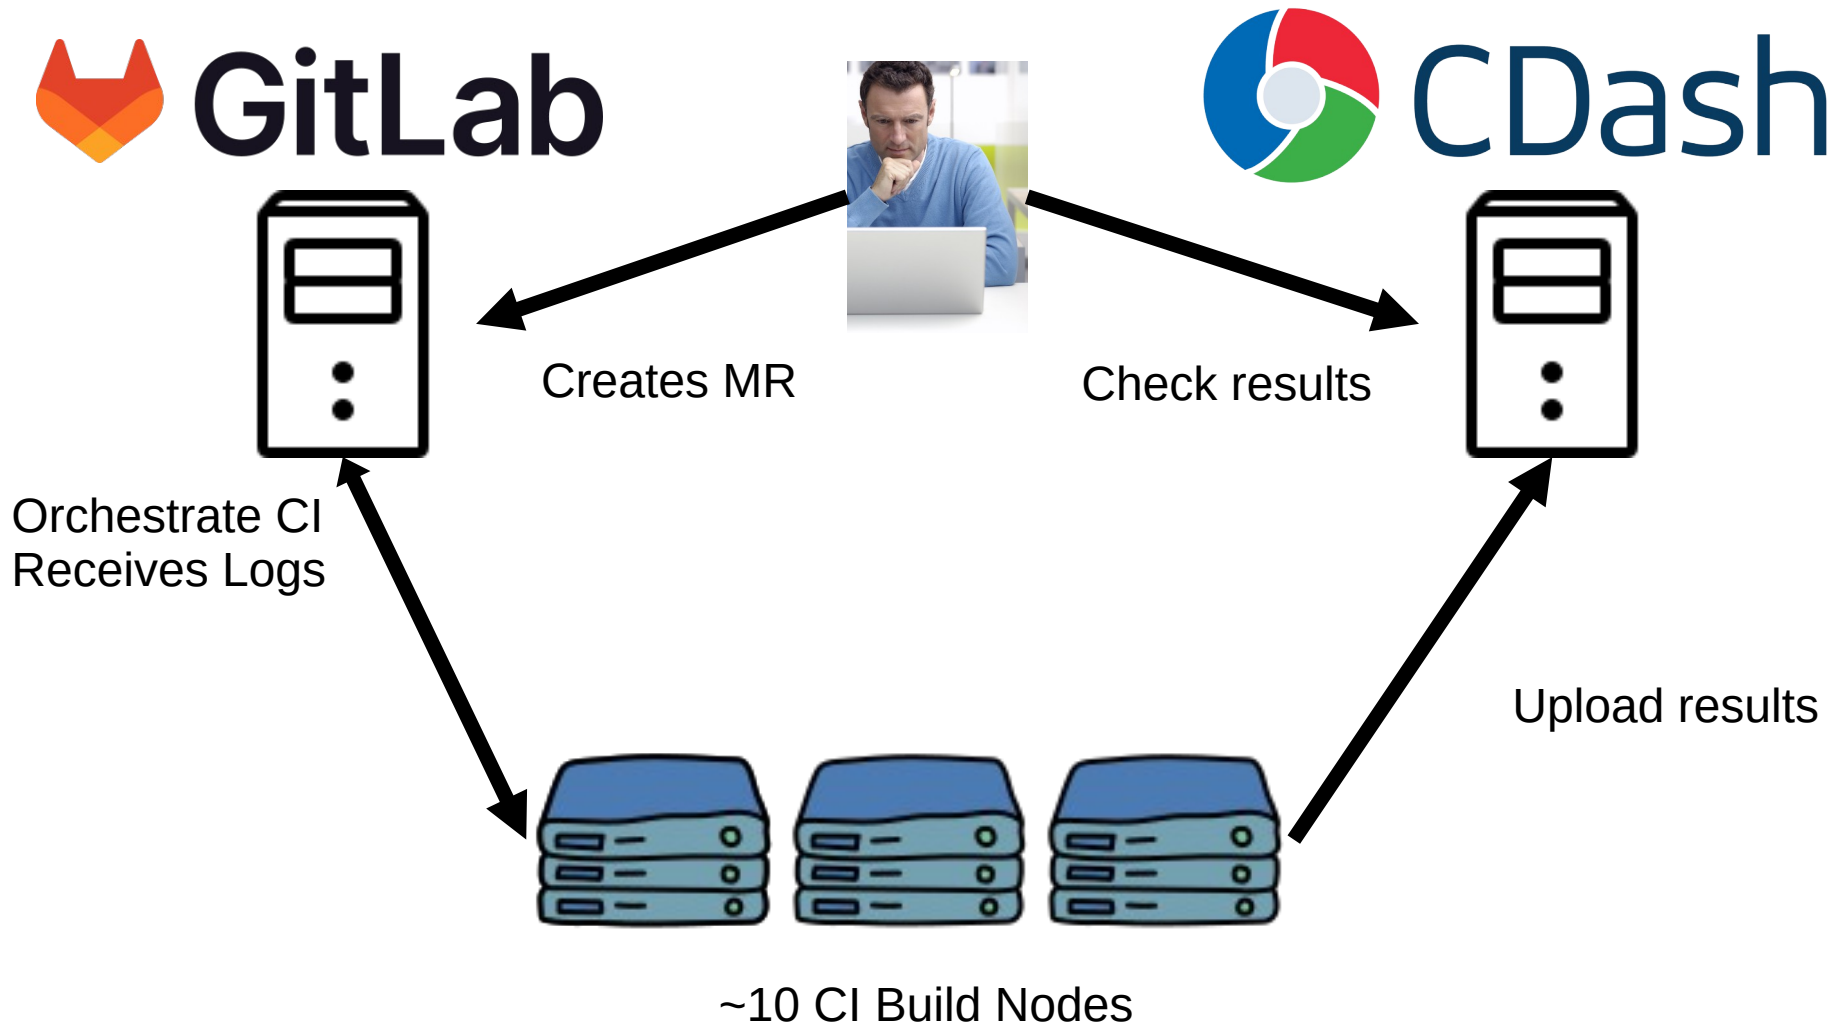

script:

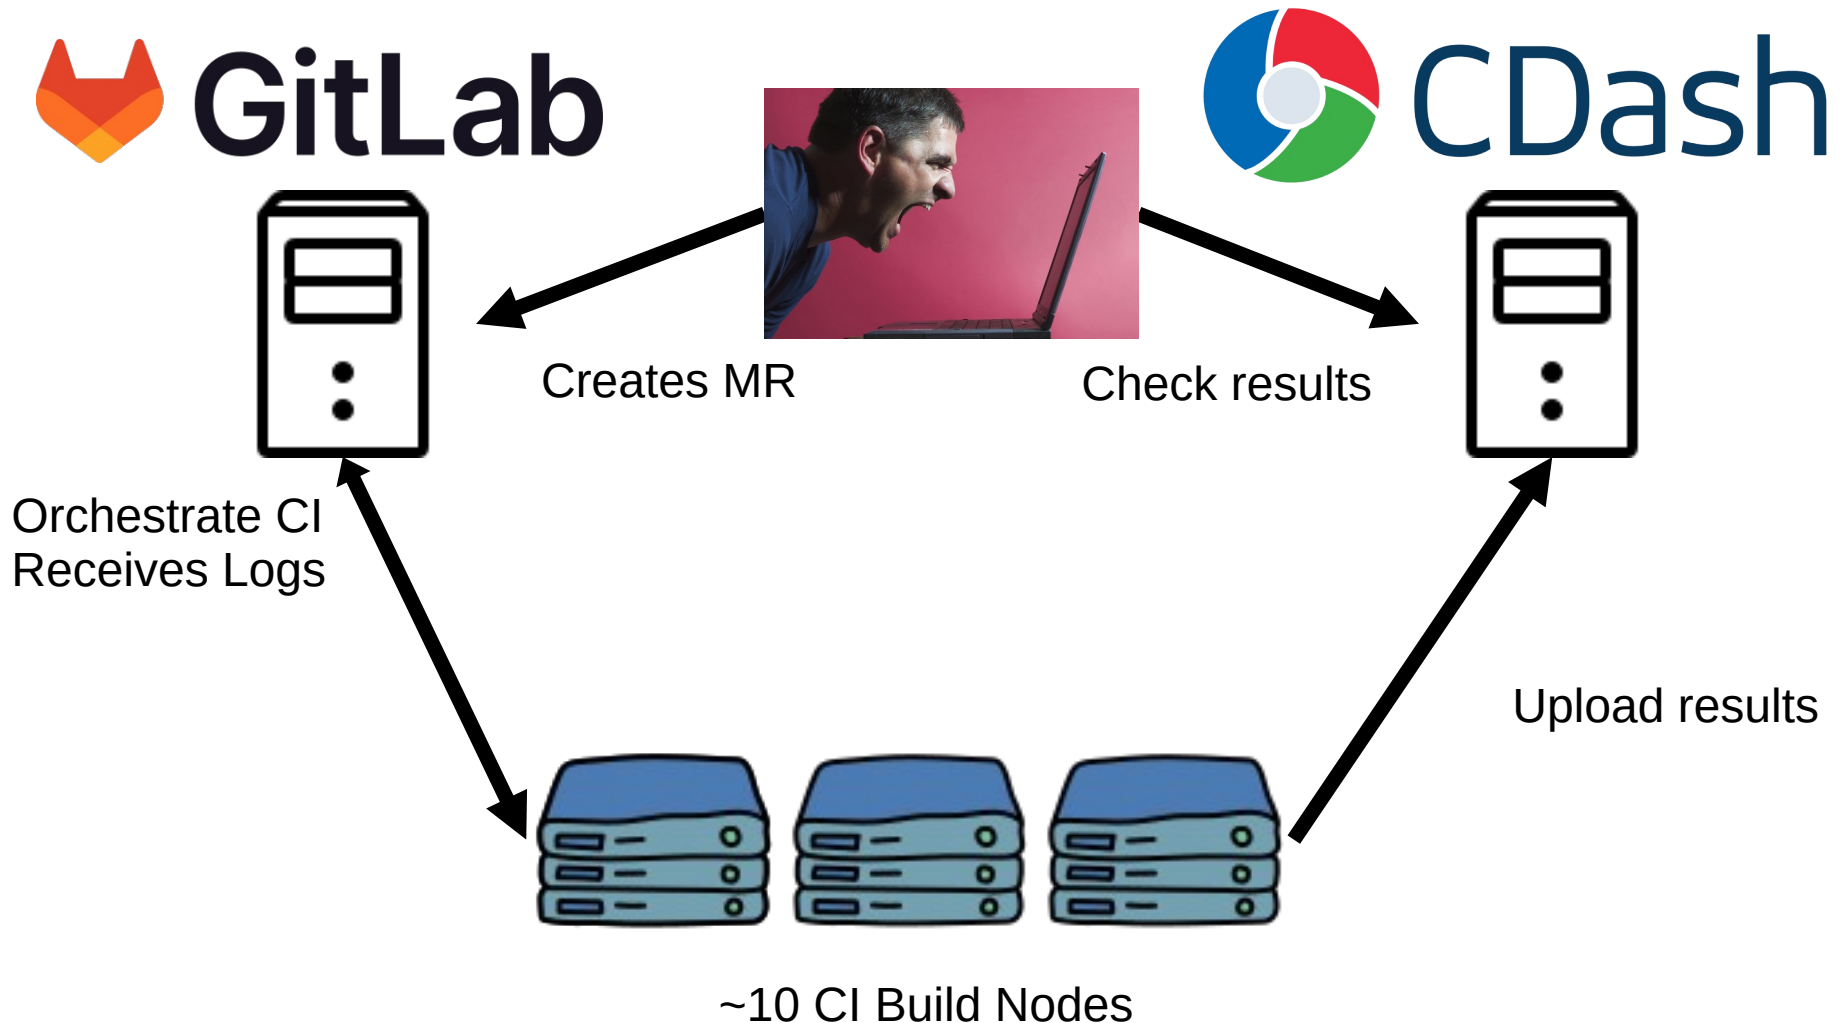

```
# Get the upstream repository manually. I did not find any other way to have it for
# comparison
# Check if a rebase is needed
# If a rebase is needed stop immediately
- apk update && apk add git bash
- scripts/connect_upstream_repo.sh $CI_MERGE_REQUEST_PROJECT_URL
- git fetch upstream
- hash1=$(git show-ref upstream/$CI_MERGE_REQUEST_TARGET_BRANCH_NAME | cut -f1 -d' ')
- hash2=$(git merge-base upstream/$CI_MERGE_REQUEST_TARGET_BRANCH_NAME HEAD)
- echo "${hash1}"
- echo "${hash2}"
- if [ "${hash1}" = "${hash2}" ]; then
-   echo "No rebase required"
-   exit 0
- else
-   echo "The Merge Request is not up-to-date"
-   echo "Rebase is required"
-   exit 1
- fi
```

Update Alpine

Connect upstream repository

Check if HEAD of upstream repo is in the history

CI Pipeline

```

- Log output helps to find problems
- At the end of some of the jobs information is also uploaded to the CDash server
 - Direct links are at the end of the log information
 - Same information can also be access from CDash

- CDash aggregates, analyses and displays the results of software testing processes
 - <https://cdash.gsi.de>
 - CbmRoot: <https://cdash.gsi.de/index.php?project=CbmRoot>
- Clients can be located anywhere world wide
 - Everybody can upload information
 - Users can provide information for systems not yet in the test matrix
- Find problems on systems you don't have access
 - For most CbmRoot users this are macosx systems
- Allows to see subtle changes over time
 - e.g. increasing test time after some code change

- CDash is very well integrated with CMake
 - No extra work to upload build and test results
- Our CMake configuration define several build targets
 - Merge Request (Is run for merge request branches)
 - Nightly (Is used for extended test suite, normally once per day)
 - Experimental (Can be used to upload local info to CDash)
 - ...
- Experimental test
 - Does not update the state of the local CbmRoot source code
 - Does not delete the build directory
 - Build CbmRoot, runs the test suite and upload the results to Cdash
 - Useful to share local problems with the CbmRoot community

```

- A little bit of CbmRoot history
 - More than 20 years of development
- Overview about complex infrastructure behind CbmRoot
 - Hope I could give you an idea about our compute infrastructure
 - Hope I don't leave you more puzzled than before
- Many tools are used and needed to manage a large software project
 - Introduce some of them
- Tried to use as many available tools as possible
 - Keep own code for infrastructure minimal
 - Add glue code to connect existing tools

- Your feedback is very welcome and actually needed
 - What can we do from the software project to help you doing your software related work?
 - Where in software and software infrastructure do you need more insight?
 - Do you think it is useful to have tutorials or hands on?
 - Which topics?
 - When and how often?
