Dilepton production in pion-nucleon and pion-nucleus reactions (CBM)

Thursday, October 16, 2014 2:40 PM (30 minutes)

We calculate electron-positron pair production in pion-nucleon and pion-nucleus collisions. Parameters of the model are fitted to pion photoproduction data. We use these cross sections in a transport model to study π -nucleus reactions. We investigate especially what is the effect of the interference between the ρ and ω mesons on the dilepton spectra. We suggest a way how experimentally the decoherence can be measured in the medium, comparing π -N, π -light nucleus and π -heavy nucleus. These results are meant to give predictions for the planned experiments at the HADES spectrometer in GSI, Darmstadt. These reactions may be studied in JPARC, too.
