

**Worm algorithms:
from loops to surfaces, from
spin models to gauge theories**

Sign2014 Darmstadt, Feb. 18, 2014

Humboldt Universität, Berlin

Spin models as loop gases

⇒ Principle demonstrated here for Ising on a D dimensional lattice

general correlation:

$$\langle \prod_x \sigma(x)^{q(x)} \rangle = \frac{Z[q]}{Z[0]}, \quad \sigma: \text{Ising spin } \pm 1, \quad q(x) \in \{0, 1\}$$

‘partition function with charges (point defects)’:

$$Z[q] = \sum_{\sigma} e^{\beta \sum_{x, \mu} \sigma(x) \sigma(x + \hat{\mu})} \prod_x \sigma(x)^{q(x)}$$

example:

$$\langle \sigma(u) \sigma(v) \rangle \quad \leftrightarrow \quad q = q_{u,v}, \quad q_{u,v}(x) = \delta_{x,u} + \delta_{x,v}$$

- global $Z(2)$ **symmetry** ⇒ $Z[q] = 0$ unless $\sum_x q(x) = \text{even}$ (**constraint**)
- use: $e^{\beta \sigma(x) \sigma(x + \hat{\mu})} = c \sum_{k=0,1} t^k [\sigma(x) \sigma(x + \hat{\mu})]^k$, $c = \cosh \beta$, $t = \tanh \beta$
- insert on **each link** ⇒ $\{k(x, \mu) \equiv k_{\mu}(x) = 0, 1\}$, **then sum-out** σ

(dropping factor $c^{\#\text{links}}$):

$$Z[q] = \sum_k t^{\sum_{x,\mu} k(x,\mu)} \delta[\partial_\mu^* k_\mu - q]$$

- constraint $\delta[\dots]$: $\sum_\mu (k(x, \mu) - k(x - \hat{\mu}, \mu)) \equiv q(x) \pmod{2}$

→loop graphs, example with $q_{u,v}$:

defect ensemble:

$$\mathcal{Z} = \sum_q R[q] Z[q] = \sum_{k, q} R[q] t^{\sum_{x, \mu} k(x, \mu)} \delta[\partial_\mu^* k_\mu - q]$$

- a priori free choice of $R[q] \geq 0$ to define \mathcal{Z} ensemble $\rightarrow \langle\langle \dots \rangle\rangle$
- only even q appear (\leftrightarrow original symmetry)

observables now by counting:

$$\langle\langle \sigma(u) \sigma(v) \rangle\rangle = \frac{\langle\langle \delta[\partial_\mu^* k_\mu - q_{u,v}] \rangle\rangle}{\langle\langle \delta[\partial_\mu^* k_\mu] \rangle\rangle} \times \frac{R[0]}{R[q_{u,v}]}$$

or

$$\frac{\langle\langle \delta[\partial_\mu^* k_\mu] \sum_{x, \mu} k(x, \mu) \rangle\rangle}{\langle\langle \delta[\partial_\mu^* k_\mu] \rangle\rangle} \leftrightarrow \text{internal energy}$$

side-remark: duality transformation \leftrightarrow

solve constraint $\partial_\mu^* k_\mu = 0$: $k_\mu = \varepsilon_{\mu\nu\lambda_1 \dots \lambda_{D-2}} \partial_\nu^* \sigma_{\lambda_1 \dots \lambda_{D-2}}$ with ‘free’ σ
 σ : spin in $D = 2$ (self-dual), gauge in $D = 3, \dots$

This step is missing for the loop ensemble....

- disjoint classes of q , $\sum_x q(x) = 0, 2, 4, 6, \dots$
- A: restrict ($R > 0$) to class 0:
 - ‘vacuum’ graphs only
 - local updates (flip $k(x, \mu)$) around plaquettes
 - critical slowing down, few observables naturally accessible
- B: allow 0 and 2 ($q \equiv q_{u,v}$ with arbitrary u, v ; 0 for $u = v$)
 - local moves of u or v (k ‘follows’ due to constraint)
 - almost no csd ← excursion to large phase space advantageous!
→ Prokof’ev and Svistunov, 2001
 - 2-point function naturally accessible
 - ‘perfect’ estimator with $R[q_{u,v}] = \rho^{-1}(u - v)$
favoring large separations

generalizations proven: Potts, XY, $O(N)$ nonlinear σ -models, $CP(N)$ models

not yet: $SU(N)$ spins ($SU(N) \times SU(N)$ invariant principle chiral models)

Gauge models as surface gases

⇒ Principle demo here for $Z(2)$ gauge model on a D dimensional lattice
 [expect \rightarrow U(1) obvious, non-Abelian, SU(3): another story...]

general correlation of gauge field $\sigma(x, \mu) = \pm 1$:

$$\left\langle \prod_{x\mu} \sigma(x, \mu)^{j(x, \mu)} \right\rangle = \frac{Z[j]}{Z[0]}, \quad \sigma(x, \mu): \text{Ising gauge } \pm 1, \quad \text{flux } j(x, \mu) \in \{0, 1\}$$

‘partition function with currents (**line defects**)’:

$$Z[j] = \sum_{\sigma} e^{\beta \sum_p \sigma_{\partial p}(x)} \prod_{x\mu} \sigma(x, \mu)^{j(x, \mu)} \quad p \leftrightarrow \text{plaquettes}$$

example, Wilson loop

$$\langle \sigma[\gamma] \rangle \quad \Leftrightarrow \quad j = j^{(\gamma)}, \quad j^{(\gamma)}(x, \mu) = \sum_{y\nu \in \gamma} \delta_{x\mu, y\nu}$$

- **local $Z(2)$ symmetry** $\Rightarrow Z[j] = 0$ unless $\partial_{\mu}^* j_{\mu}(x) = 0 \pmod{2}$
- center symm. on torus $\Rightarrow Z[j] = 0$ unless $\sum_{x, x_{\mu} \text{ fixed}} j_{\mu}(x) = \text{even}$
- use: $e^{\beta \sigma_{\partial p}} = c \sum_{k=0,1} t^k [\sigma(l_1)\sigma(l_2)\sigma(l_3)\sigma(l_4)]^k$, $c = \cosh \beta$, $t = \tanh \beta$
- insert **on each plaq.** $\Rightarrow \{k(x; \mu, \nu) \equiv k_{\mu\nu}(x) = 0, 1\}$, then **sum-out σ**

(dropping factor $c^{\#\text{plaqs}}$):

$$Z[j] = \sum_k t^{\sum_{x,\mu} k(x;\mu,\nu)} \delta[\partial_\mu^* k_{\mu\nu} - j_\nu]$$

- constraint $\delta[\dots]$: $\sum_\mu (k(x; \mu, \nu) - k(x - \hat{\mu}; \mu, \nu)) \equiv j(x, \nu) \pmod{2}$

→ surface graphs, 3D example with $j \leftrightarrow 2$ Polyakov lines:

defect ensemble:

$$\mathcal{Z} = \sum_j R[j] Z[j] = \sum_{k,j} R[j] t^{\sum_{x,\mu,\nu} k(x;\mu,\nu)} \delta[\partial_\mu^* k_{\mu\nu} - j_\nu]$$

now the analogy fades a bit....

which j do we want to allow (choice of R)??

- allowed: $j(x, \mu)$ divergence free (e.g. closed loop) + center symmetry (no odd winding number)
- !: include small defect networks, returning to vacuum sometimes

unsuccessful experiments with regard to csd in $D = 3$ at β_c :

- $R[j] \propto e^{-\alpha \sum_{x,\mu} j(x,\mu)} \leftrightarrow$ chemical potential to control defects
- either: single (self-avoiding) closed loop, or: arbitrary allowed j
- legal algos, correct, α does the job, but NOT FAST at β_c
- there are a lot more loop than point defects

moreover:

- ensemble of irregular fuzzy loop(s):
can they be connected to ‘useful’ observables?
- e.g. string tension from fluctuating Wilson loops (not rectangular)?

Perfect Polyakov line correlation

- csd cannot be overcome at the moment ($z \approx 2$)
- but **improved observables available** in

$$\mathcal{Z} = \sum_{\vec{u}, \vec{v}, k} R(\vec{u} - \vec{v}) t^{\sum_{x, \mu, \nu} k(x; \mu, \nu)} \delta \left[\partial_{\mu}^* k_{\mu\nu} - j_{\nu}^{(\vec{u}, \vec{v})} \right]$$

- $j^{(\vec{u}, \vec{v})}$ defect \leftrightarrow 2 lines in 0-direction at \vec{u} and \vec{v} in $(D - 1)$ -space

$$\langle \pi(\vec{x}) \pi(\vec{0}) \rangle = R^{-1}(\vec{x}) \frac{\langle \langle \delta_{\vec{x}, \vec{u} - \vec{v}} \rangle \rangle}{\langle \langle \delta_{\vec{u}, \vec{v}} \rangle \rangle}$$

- update steps amalgam of:
 - flip $k(x; \mu, \nu) \rightarrow 1 - k(x; \mu, \nu)$ around 3-cubes, good acceptance
 - shift lines: propose $\vec{u} \rightarrow \vec{u} \pm \hat{i}$ & flip ‘ladder’ of plaquettes
 - ok acceptance up to 64^3 (β_c) and 48×64^2 ($\beta < \beta_c$)
 - non-rejecting shifts[Liu, Deng, Garoni]:
different ensemble $\mathcal{Z}' \neq \mathcal{Z}$, weight of vacuum graphs unchanged
- line-shift step can **change wrapping number of surfaces**
 \leftrightarrow ratio $Z_{\text{twisted bc}}/Z = \langle \langle \dots \rangle \rangle$ well measurable

- \rightarrow opportunity to precision match gauge theory \leftrightarrow [effective string model](#)
- details: see my lat13 talk

A few conclusions

- worm or strong coupling graph simulation method
 - straight-forward to generalize spins \rightarrow abelian gauge model
 - not so efficient for csd (do we miss the essential trick?)
 - line defects different story from point defects....
- Taylor ensemble to observables
 - this does generalize successfully
 - Polyakov loop correlation decay traced over many orders
- fermions: no news, see sign 2012
