

Transition energy variation in antiproton mode of CR

Oleksii Gorda

**BINP-FAIR-GSI 6th workshop, GSI
2 December 2014**

Antiprotons at FAIR

Initially planned scenario for pbars:

- stochastic pre-cooling in CR
- accumulation by longitudinal stacking in combination with stochastic cooling in RESR
- delivery to HESR or NESR for acceleration/deceleration and experiments

Modularized Start Version (MSV) of FAIR:

- stochastic pre-cooling in CR
- barrier bucket accumulation with stochastic cooling in HESR

Beam parameters

Table 2.5-51: Required stochastic cooling performance in the CR.

	Antiprotons 3 GeV, 10^8 ions		Rare isotopes/stable heavy ions 740 MeV/u, cooling of 10^8 ions	
	$\delta p/p$ (rms)	$\epsilon_{h,v}$ (rms) [π mm mrad]	$\delta p/p$ (rms)	$\epsilon_{h,v}$ (rms) [π mm mrad]
Before/after cooling	0.35 % / 0.05 %	40 / 1.25	0.2 % / 0.025 %	35 / 0.125
Phase space reduction	7×10^3		6×10^5	
Cooling time	≤ 9 s / 10 s		≤ 1 s / 1.5 s	

* CR TDR 2013

CR beam parameters

	$\delta p/p$ (rms)
Momentum spread after cooling in CR	5×10^{-4}
Momentum acceptance of stochastic cooling system in HESR*	6×10^{-4}

* assuming 99% of particles within a given distribution

HESR requirements

CR Beam Quality Requirements for the HESR
H. Stockhorst, B. Lorentz
11.12.13

The standard HESR lattice with $\gamma_L = 6.23$ is used for injection of stable ions (bare uranium or tin) as well as injection and accumulation of anti-protons delivered from the Collector Ring (CR). In this mode the HESR has the

- **Transverse acceptance** (see for comments below):
15.4 mm meridional (horizontal and vertical)
- **Longitudinal momentum acceptance** (see for comments below):
 $\Delta p/p = 2.5 \cdot 10^{-2}$

The momentum acceptance of stochastic cooling (SC):

SC momentum acceptance $\Delta p/p$	SC method	Kinetic Energy [MeV/u]	Particle Type
$2.1 \cdot 10^{-2}$	Filter	3000	anti-protons
$2.7 \cdot 10^{-2}$	TOF	740	ions

Table 1: Stochastic momentum cooling acceptance

The application of stochastic cooling for anti-proton accumulation at 3 GeV or the ion beam preparation at 740 MeV/u limits the acceptable momentum spread in the beam bunch delivered by the CR.

The DC beam in the CR is additionally re-bunched. The bunched beam is then extracted to the HESR with the CR extraction kicker. The re-bunching voltage must be high enough to provide the necessary kicker gap (kicker rise time = 200 ns) in the CR. Due to re-bunching the momentum spread is increased.

After the re-bunching procedure the rms relative momentum spread of the bunched beam must be smaller than the following values:

Kinetic Energy [MeV/u]	rms rel. Momentum Spread [$\Delta p/p$]	Particle Type
3000	$< 6 \cdot 10^{-4}$ (see note below)	anti-protons
740	$< 2 \cdot 10^{-3}$ (see note below)	ions

Table 2: Required minimum rms relative momentum spread of the transferred CR beam bunch

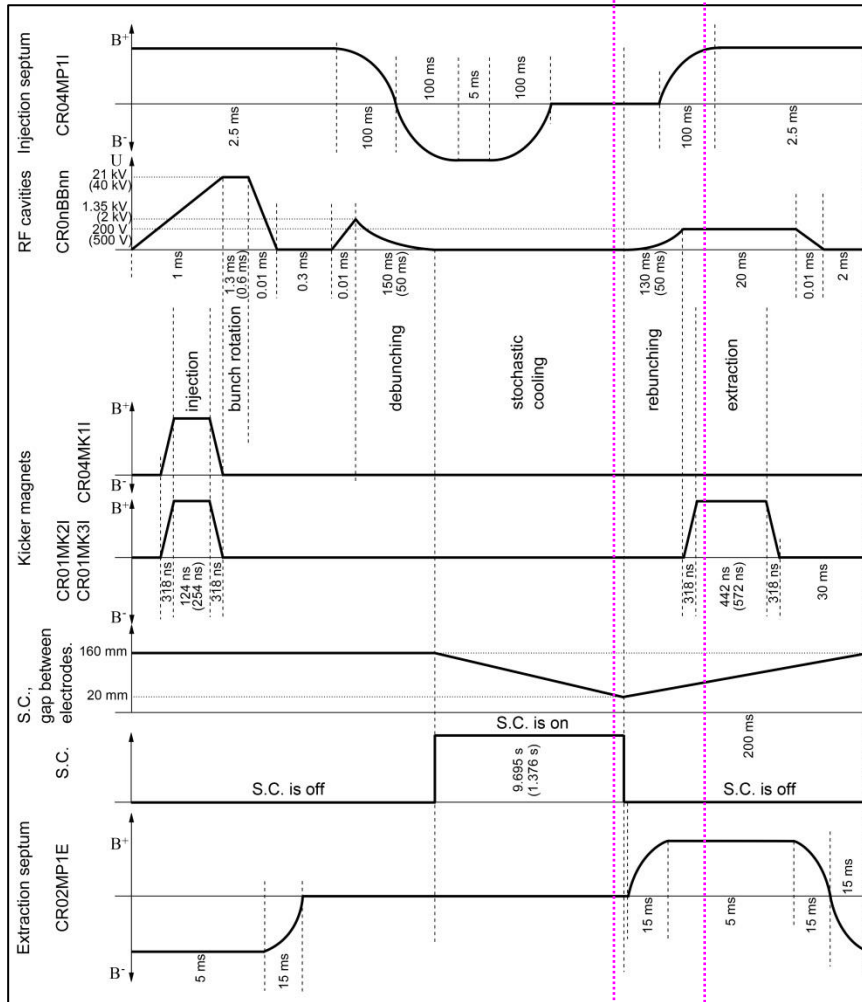

If these values are exceeded particles outside the SC acceptance will not be cooled. If the cooling acceptance should not be exceeded.

one assumes that the transferred bunch has a Gaussian momentum distribution with momentum spread $(\Delta p/p)_{\text{rms}}$, then one must require that $3 \cdot (\Delta p/p)_{\text{rms}} < \delta_p$, since the

* HESR internal notes 2013

... after rebunching

CR operation cycle

*as given in TDR 2013

- Cooling → rebunching → extraction to HESR.
- During the rebunching the momentum spread is increased by a factor of 2 (?).
- Numerical simulations by Jülich colleagues (for beam parameters given in TDR 2013) :

About 30% of pbars are out of acceptance of HESR stochastic cooling system, and will be lost due to heating.

- Possible mitigations?

Possible improvements

GSI - Minutes		Nr.: 20140702	
Minutes of the 5th FAIR/GSI/BiNP Workshop at GSI on Wednesday, 2 nd of July 2014		Name: Oleksiy Dolinskyy	
Distribution:		
Attendees:	C. Dimopoulou, O. Dolinskyy, M. Dolinska, O. Gorda, D. Berkaev, W. Jacoby, P. Shatalnov, I. Koop, D. Prasuhn, H. Stockhert, R. Stassen.		
Important:	<u>How to treat this document:</u> <u>I: Information (by xyl)</u> <u>P: Presentation</u> <u>R: Remark</u> <u>D: Decision</u> <u>Q: Question</u> <u>A: Action Item</u>		
Topic	Due Date	Responsible	
1. Beam parameters needed for HESR			
1.1		I (H. Stockhert)	
<p>The planned Stochastic Cooling at HESR will be used for pbar-accumulation at 3 GeV and the ion beam preparation at 740 MeV/u, which are delivered directly from CR in MSV of the FAIR project. The present design of the HESR has the transverse acceptance of 16 mm²mrad and longitudinal momentum acceptance $\Delta p/p$ of $\pm 2.8 \times 10^{-4}$. The momentum transverse acceptance cooling at HESR depends on the momentum acceptance cooling at HESR: this value is $\pm 2.8 \times 10^{-4}$ for pbar and $\pm 2.8 \times 10^{-4}$ for CR special ion.</p>			
<p>1.2 Q (O. Dolinskyy)</p> <p>What is determination of the beam parameters?</p>			
<p>1.3 R (H. Stockhert)</p> <p>It is assumed that 99% of particles within cooling acceptance are lost. It is important to keep the pbar within cooling acceptance. The relative momentum spread of bunched beam must be smaller than 6×10^{-4} for pbar and 2×10^{-4} for CR special ion.</p>			
<p>2. Present status, requirement to CR system</p>			
<p>2.1 I (C. Dimopoulou)</p> <p>The SC at CR was optimized for precooling of hot ions coming from separators with subsequent delivering to RESR, where the accumulation and further cooling take place. According to specified requirements the SC at CR can provide the following:</p>			

- Reduce the rise time of the kicker magnets from 318 ns (CR TDR 2013) to 200 ns or even less?
- Consider plunging of pick-up electrodes in simulations. Check whether cooling in longitudinal space could be improved?
- Applying of combined TOF and Notch filter methods for stochastic cooling of antiprotons in HESR.
- **Improve the cooling efficiency in CR by a variation of the mixing parameter (or the transition energy) during the cooling process.**

Discussion on beam parameters required for HESR,
5th BINP-FAIR-GSI workshop,
2 July, 2014

GSI and BINP optics

GSI

Parameter	Value
Lorentz γ	4.20
Transition γ_{tr}	3.85
Momentum compaction η	-0.011
Betatron tunes Q_x/Q_y	4.09/4.34

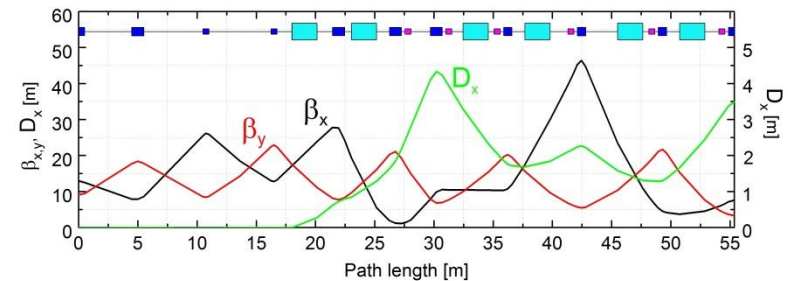

- Variation of transition energy in the range of $3.85 \geq \gamma_{tr} \geq 3.35$ corresponding to the momentum compaction $-0.011 \geq \eta \geq -0.03$

$$\eta = \frac{1}{\gamma^2} - \frac{1}{\gamma_{tr}^2} \quad \text{with} \quad \frac{1}{\gamma_{tr}^2} = \frac{1}{C} \int_0^C \frac{D_x(s)}{\rho(s)} ds, C - \text{ring circumference}$$

- Average dispersion D_x has to be increased.

BINP

Parameter	Value
Lorentz γ	4.20
Transition γ_{tr}	4.84
Momentum compaction η	0.013
Betatron tunes Q_x/Q_y	4.18/3.23

- Variation of transition energy in the range of $4.84 \leq \gamma_{tr} \leq 6.2$ corresponding to the momentum compaction $0.013 \leq \eta \leq 0.03$

- Average dispersion D_x has to be decreased.

Y_{tr} variation (GSI optics)

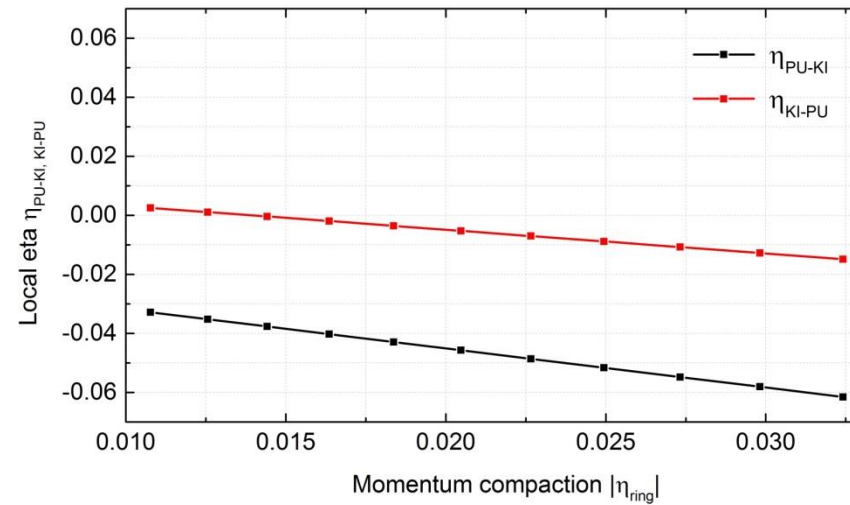

- 7 families of quads are used.
- Phase advance $\Delta\mu = \pi/2$ between SC pick-ups and kickers is controlled during ramping.
- Betatron tunes Q_x, Q_y are constant during ramping to avoid cross of resonances.
- Dispersion $D_x=0$ in the straight sections is adjusted during ramping.

Required ramp rate:

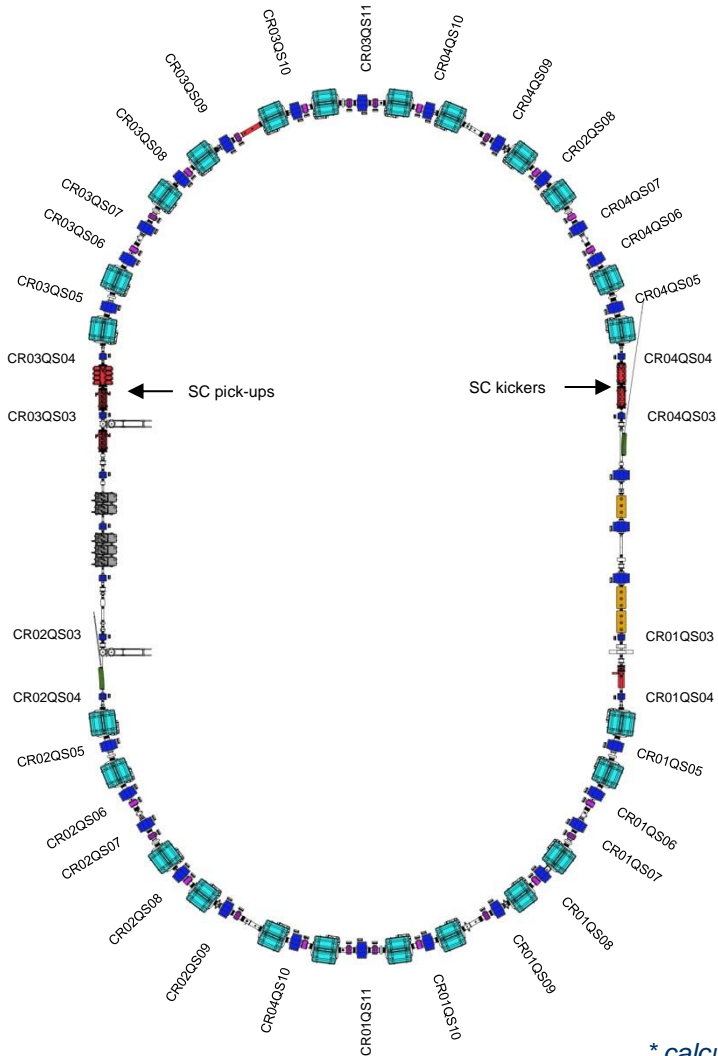

Ramping time	10 s	8 s	5 s	3 s
Max. gradient rate, T/m/s, WQ	0.12	0.15	0.24	0.4
Max. gradient rate, T/m/s, NQ	0.07	0.09	0.14	0.23

Local η variation (GSI optics)

γ_{tr} variation (BINP optics)

- 9 families of quads are used.
- Phase advance $\Delta\mu = \pi/2$ between SC pick-ups and kickers is controlled during ramping.
- Betatron tunes Q_x, Q_y are constant during ramping to avoid cross of resonances.
- Dispersion $D_x=0$ in the straight sections is adjusted during ramping.

Required ramp rate:

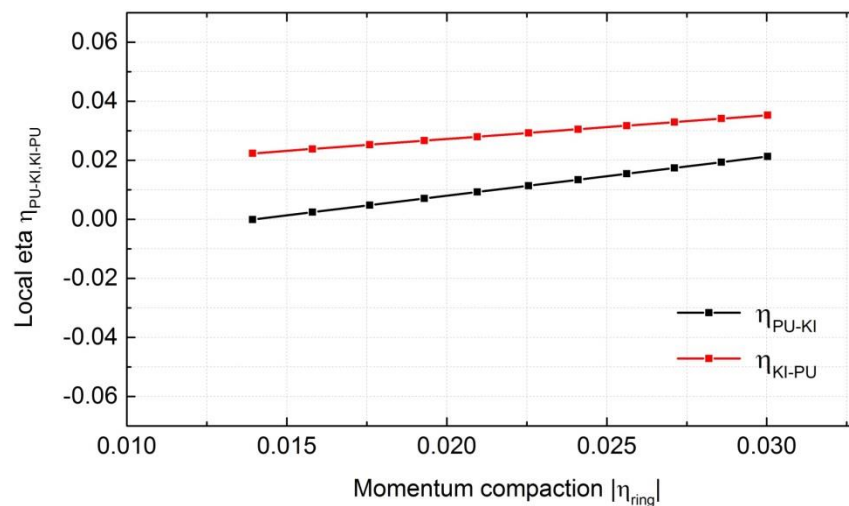

Ramping time	10 s	8 s	5 s	3 s
Max. gradient rate, T/m/s, WQ	0.12	0.15	0.24	0.4
Max. gradient rate, T/m/s, NQ	0.04	0.05	0.08	0.13

* calculations by S. Litvinov

Quadrupole ramping

Local η variation (BINP optics)

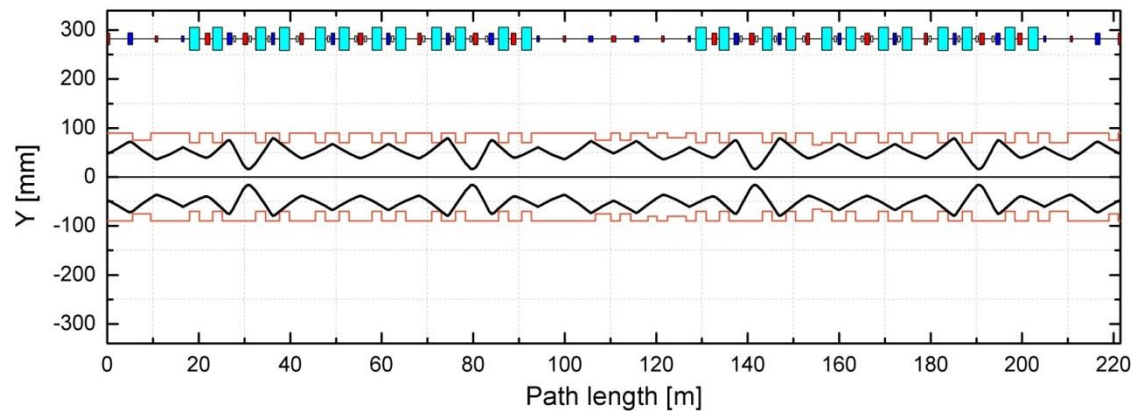

** calculations by S. Litvinov*

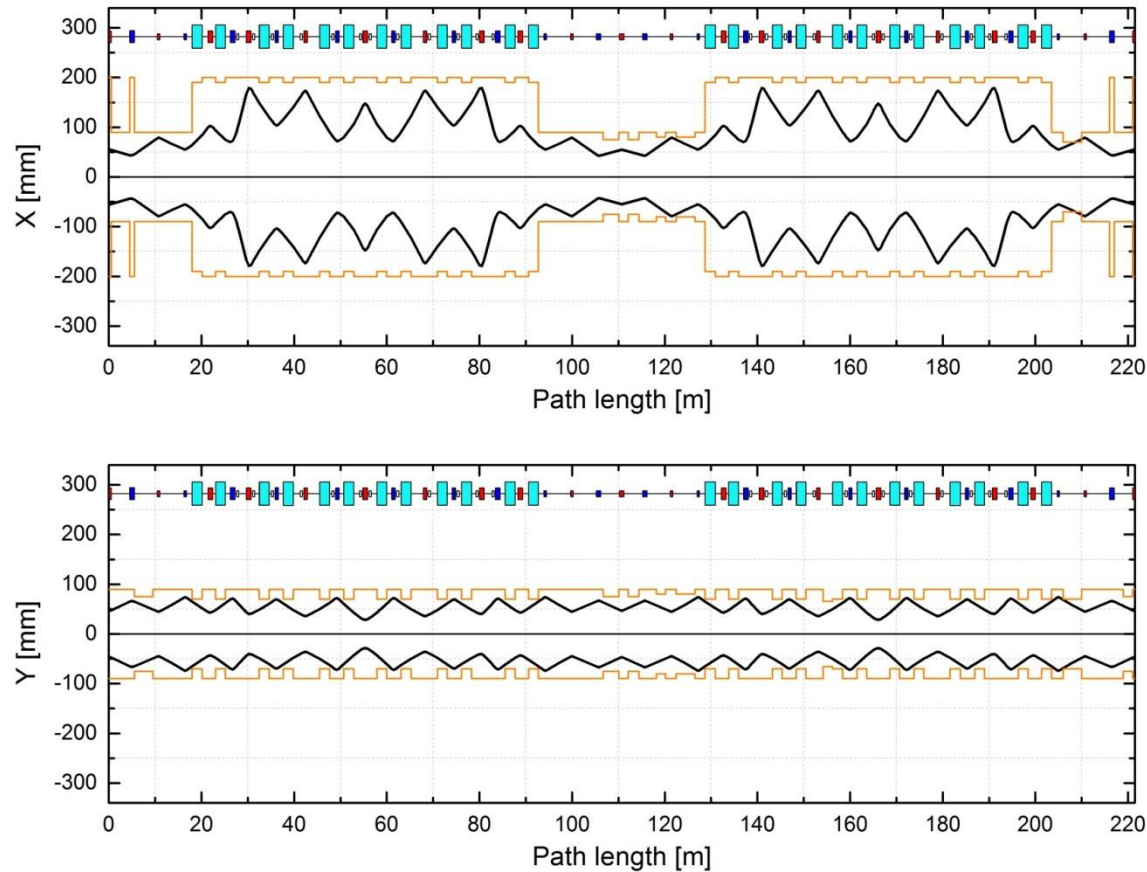

Short summary

- Momentum compaction can be varied in range of $0.011 \leq |\eta| \leq 0.33$ in both GSI and BINP pbar-optics.
- Control parameters during ramping:
 - phase advance between SC PU and KI,
 - betatron tunes,
 - dispersion in the straight sections.
- Quadrupole current limits have to be taken into account.
- Calculations for latest ion-optics.
