UPPSALA  
UNIVERSITET

FAIRNESS 2017 at Sitges, Spain

28 May – 3 June

## 1 Motivation

## 2 The Density Matrix and Polarization Parameters

- *spin 1/2*
- *spin 3/2*

## 3 The Angular Distributions

- *spin 1/2* → *spin 1/2 spin 0*
- *spin 1/2* → *spin 1/2 spin 0* → *spin 1/2 spin 0 spin 0*
- *spin 3/2* → *spin 1/2 spin 0*
- *spin 3/2* → *spin 1/2 spin 0* → *spin 1/2 spin 0 spin 0*

## 4 Summary and Outlook

# Before starting: Hyperons

- Nucleons siblings:

→ replace up/down by strange quark → **octet hyperons** ( $J^P = \frac{1}{2}^+$ )

→ replace up/down by strange quark + flip spin → **decuplet hyperons** ( $J^P = \frac{3}{2}^+$ )

(Gell-Mann's multiplet assignments)

# Motivation

The PANDA experiment will allow to study for the first time the reaction:

$\Omega$ 's features:

- spin 3/2 particle according to quark model (not yet confirmed by experiment!)
- triple strangeness hyperon
- can be used to test baryon CP violation in weak decays

GOAL:

The **polarization parameters**  $r_M^L$  of the  $\Omega$  can be extracted making use of the angular distributions of:

$\Omega$  decay + subsequent decay of the daughter  $\Lambda$

$$i.e. \quad \Omega \rightarrow \Lambda K \quad \text{and} \quad \Lambda \rightarrow p\pi$$

# The Density Matrix

For a pure state the expectation value of an observable  $E$  is given by

$$\langle E \rangle = \langle \Psi | E | \Psi \rangle$$

In an orthonormal basis  $\{|a_k\rangle\}$  can be rewritten as

$$\begin{aligned} \langle E \rangle &= \langle \Psi | \left( \sum_k |a_k\rangle \langle a_k| \right) E | \Psi \rangle = \sum_k \langle \Psi | a_k \rangle \langle a_k | E | \Psi \rangle \\ &= \sum_k \langle a_k | E | \Psi \rangle \langle \Psi | a_k \rangle = \text{Tr}(E | \Psi \rangle \langle \Psi |) \end{aligned}$$

Define  $\rho = |\Psi\rangle \langle \Psi|$ , then

$$\langle E \rangle = \text{Tr}(E\rho)$$

Generalization for a mixed state:

$$\langle E \rangle = \text{Tr} \left( E \sum_i a_i |\Psi_i\rangle \langle \Psi_i| \right)$$

where  $\rho$  is now defined as  $\rho = \sum_i a_i |\Psi_i\rangle \langle \Psi_i|$

# The Density Matrix

For a particle with spin  $j$  the **density matrix** is given by

$$\rho = \frac{1}{2j+1} \mathcal{I} + \sum_{L=1}^{2j} \rho^L$$

$$\text{with } \rho^L = \frac{2j}{2j+1} \sum_{M=-L}^L Q_M^L r_M^L$$

where  $\mathcal{I}$  is the identity matrix,  $Q_M^L$  is a set of hermitian matrices and  $r_M^L$  are the polarization parameters.

$$\text{Particle's degree of polarization: } d(\rho) = \sqrt{\sum_{L=1}^{2j} \sum_{M=-L}^L (r_M^L)^2}$$

- Spin 1/2: **3** polarization parameters ( $L=1 \quad -L < M < L$ )
- Spin 3/2: **15** polarization parameters ( $L=1,2,3 \quad -L < M < L$ )

Doncel *et al.*, Phys.Rev. D7, 815 (1973)

# The Density Matrix (spin 1/2)

- $Q_M^1 \rightarrow$  Pauli matrices  $\vec{\sigma} = (\sigma_1, \sigma_2, \sigma_3)$
- $r_M^1 \rightarrow$  vector polarization  $\vec{P} = (P_x, P_y, P_z)$

$$\rho(1/2) = \begin{bmatrix} \rho_{11} & \rho_{1-1} \\ \rho_{-11} & \rho_{-1-1} \end{bmatrix} = \frac{1}{2}(\mathcal{I} + \vec{P} \cdot \vec{\sigma}) = \frac{1}{2} \begin{bmatrix} 1 + P_z & P_x - iP_y \\ P_x + iP_y & 1 - P_z \end{bmatrix}$$

For hyperons produced at e.g. PANDA:

- $\bar{p}p \rightarrow \bar{Y}Y$
- strong interaction
- unpolarized beam and target

the density matrix must fulfil symmetries due to parity conservation

$$\begin{aligned} \rho(1/2) &= \begin{bmatrix} \rho_{11} & \rho_{1-1} \\ -\rho_{1-1} & \rho_{11} \end{bmatrix} \\ &= \frac{1}{2} \begin{bmatrix} 1 & -iP_y \\ iP_y & 1 \end{bmatrix} \end{aligned}$$

*i.e.*  $P_x = P_z = 0$

Polarization normal to the production plane!

# The Density Matrix (spin 3/2)

It gets more complicated now...

- 15  $r_M^L$  parameters (L=1,2,3)

However thanks to the symmetries imposed on the  $\rho$  by parity conservation in the creation mechanism:

→ 8 of the 15  $r'_s$  can be set to zero

We are left with:

$$\rho(3/2) = \frac{1}{4} \begin{bmatrix} 1 + \sqrt{3}r_0^2 & -i\frac{3}{\sqrt{5}}r_{-1}^1 + \sqrt{3}r_1^2 - i\sqrt{\frac{6}{5}}r_{-1}^3 & \sqrt{3}r_2^2 - i\sqrt{3}r_{-2}^3 & -i\sqrt{6}r_{-3}^3 \\ i\sqrt{\frac{6}{5}}r_{-1}^3 + i\frac{3}{\sqrt{5}}r_{-1}^1 + \sqrt{3}r_1^2 & 1 - \sqrt{3}r_0^2 & -i2\sqrt{\frac{3}{5}}r_{-1}^1 + i3\sqrt{\frac{2}{5}}r_{-1}^3 & \sqrt{3}r_2^2 + i\sqrt{3}r_{-2}^3 \\ \sqrt{3}r_2^2 + i\sqrt{3}r_{-2}^3 & i2\sqrt{\frac{3}{5}}r_{-1}^1 - i3\sqrt{\frac{2}{5}}r_{-1}^3 & 1 - \sqrt{3}r_0^2 & -i\frac{3}{\sqrt{5}}r_{-1}^1 + \sqrt{3}r_1^2 - i\sqrt{\frac{6}{5}}r_{-1}^3 \\ i\sqrt{6}r_{-3}^3 & \sqrt{3}r_2^2 - i\sqrt{3}r_{-2}^3 & i\frac{3}{\sqrt{5}}r_{-1}^1 + \sqrt{3}r_1^2 + i\sqrt{\frac{6}{5}}r_{-1}^3 & 1 + \sqrt{3}r_0^2 \end{bmatrix}$$

→ To get the polarization, the **7** remaining  $r$  coefficients need to be measured

Erik Thomé, Ph.D. Thesis, Uppsala University (2012)

# Angular Distributions for Hyperons Decays

- Introduce decay matrix  $T$  such that  $T |\Psi_i\rangle = |\Psi_f\rangle$
- Recall that  $\rho = |\Psi\rangle \langle\Psi|$

The transformation of the density matrix is performed by the  $T$  matrix :

$$\rho_{\text{final}} = T \rho_{\text{initial}} T^\dagger$$

The angular distribution of the daughter particle is given by:

$$I = \text{Tr}(T \rho_{\text{initial}} T^\dagger)$$

## spin 1/2 $\rightarrow$ spin 1/2 spin 0

For weak decay both the parity conserving P state and the parity violating S state are allowed:

$$T(1/2 \rightarrow 1/2 0) = \frac{1}{\sqrt{4\pi}} \begin{bmatrix} T_s + T_p \cos \theta & T_p \sin \theta e^{-i\phi} \\ T_p \sin \theta e^{i\phi} & T_s - T_p \cos \theta \end{bmatrix}$$

Using cyclicity of the trace:  $\text{Tr}(T\rho T^\dagger) = \text{Tr}(\rho T^\dagger T)$ , where:

$$T^\dagger T = A(1/2 \rightarrow 1/2 0) = \frac{1}{4\pi} \begin{bmatrix} 1 + \alpha \cos \theta & \alpha \sin \theta e^{-i\phi} \\ \alpha \sin \theta e^{i\phi} & 1 - \alpha \cos \theta \end{bmatrix}$$

Asymmetry parameters:

$$\alpha = 2\text{Re}(T_s^* T_p)$$

$$\beta = 2\text{Im}(T_s^* T_p)$$

$$\gamma = |T_s|^2 - |T_p|^2$$

where by construction  $\alpha^2 + \beta^2 + \gamma^2 = |T_s|^2 + |T_p|^2 = 1$

# spin 1/2 $\rightarrow$ spin 1/2 spin 0

The angular distribution is:

$$I(\theta, \phi) = \text{Tr}(\rho(1/2)A(1/2 \rightarrow 1/2 0)) = \frac{1}{4\pi}(1 + \alpha P_y \sin \theta \sin \phi)$$

or equivalently  $I(\cos \theta_p) = \frac{1}{4\pi}(1 + \alpha P_y \cos \theta_p)$

**Polarization** of the spin 1/2 hyperon  
**experimentally accessible** from the  
angular distribution of the decay products!

*spin 1/2* → *spin 1/2 spin 0* → *spin 1/2 spin 0 spin 0*

Some hyperons decay to states which also include hyperons, e.g.

$$\mathbf{1} : \Xi \rightarrow \Lambda\pi \quad \rightarrow \quad \mathbf{2} : \Lambda \rightarrow p\pi$$

Using two decay matrices ( $T_1$ ,  $T_2$ ) we gain additional information!

The joint angular distribution is obtained as:

$$I = \text{Tr}(T_2 R T_1 \rho T_1^\dagger R^\dagger T_2^\dagger) = \text{Tr}(\rho T_1^\dagger R^\dagger A_2 R T_1)$$

A rotation  $R$  is performed to make the spins in the two decays defined with respect to the same axis

$$R = e^{-i\frac{1}{2}\phi_\Lambda\sigma_z} e^{i\frac{1}{2}\theta_\Lambda\sigma_y} e^{i\frac{1}{2}\phi_\Lambda\sigma_z} = \begin{bmatrix} \cos\frac{\theta_\Lambda}{2} & \sin\frac{\theta_\Lambda}{2} e^{-i\phi_\Lambda} \\ -\sin\frac{\theta_\Lambda}{2} e^{i\phi_\Lambda} & \cos\frac{\theta_\Lambda}{2} \end{bmatrix}$$

*spin 1/2*  $\rightarrow$  *spin 1/2 spin 0*  $\rightarrow$  *spin 1/2 spin 0 spin 0*

By integrating over  $\theta_\Lambda$  and  $\phi_\Lambda$  we get the angular distribution of the second decay:

$$I(\theta_p, \phi_p) = \frac{1}{4\pi} \left( 1 + \alpha_\Xi \alpha_\Lambda \cos \theta_p + \frac{1}{2} \alpha_\Lambda P_y \sin \theta_p (\beta_\Xi \cos \phi_p + \gamma_\Xi \sin \phi_p) \right)$$

where also  $\beta_\Xi$  and  $\gamma_\Xi$  show up!

## spin 3/2 $\rightarrow$ spin 1/2 spin 0

For weak decay both the parity conserving P state and the parity violating D state are allowed  
 $\rightarrow T(3/2 \rightarrow 1/2 0)$  matrix in terms of  $T_p$  and  $T_d$

The angular distribution is:

$$\begin{aligned} I(\theta, \phi) &= \text{Tr}(\rho(3/2)A(3/2 \rightarrow 1/2 0)) \\ &= \frac{1}{4\pi} \left[ 1 + \frac{\sqrt{3}}{2} (1 - 3 \cos^2 \theta) r_0^2 - \frac{3}{2} \sin^2 \theta \cos 2\phi r_2^2 - \frac{3}{2} \sin 2\theta \cos \phi r_1^2 \right. \\ &\quad + \frac{1}{40} \alpha \sin \theta \left( 8\sqrt{15} r_{-1}^1 \sin \phi - 9\sqrt{10} r_{-1}^3 (3 + 5 \cos 2\theta) \sin \phi \right. \\ &\quad \left. \left. - 30(3r_{-2}^3 \sin 2\phi \sin 2\theta + \sqrt{6} r_{-3}^3 \sin 3\phi \sin^2 \theta) \right) \right] \end{aligned}$$

For the  $\Omega^- \rightarrow \Lambda K^-$  decay:  $\alpha = 0.0180 \pm 0.0024$  [PDG]

- polarization parameters are accessible using e.g. the Method of Moments

A.Frodesen, O.Skeggestad and H.Tofte, *Probability and Statistics in Particle Physics*, Bergen (1979)

# Method of Moments

From the angular distribution of the  $\Lambda$  coming from the  $\Omega \rightarrow \Lambda K$  decay, the polarization parameters  $r_0^2$ ,  $r_1^2$ ,  $r_2^2$  can be retrieved:

$$\begin{aligned}\langle \sin \theta_\Lambda \rangle &= \int I(\theta_\Lambda, \phi_\Lambda) \times \sin \theta_\Lambda d\Omega_\Lambda \\ &= \frac{\pi}{32} (8 + \sqrt{3} r_0^2)\end{aligned}$$

$$\begin{aligned}\langle \cos \phi_\Lambda \cos \theta_\Lambda \rangle &= \int I(\theta_\Lambda, \phi_\Lambda) \times \cos \phi_\Lambda \cos \theta_\Lambda d\Omega_\Lambda \\ &= -\frac{3\pi}{32} r_1^2\end{aligned}$$

$$\begin{aligned}\langle \sin^2 \phi_\Lambda \rangle &= \int I(\theta_\Lambda, \phi_\Lambda) \times \sin^2 \phi_\Lambda d\Omega_\Lambda \\ &= \frac{1}{4} (2 + r_2^2)\end{aligned}$$

*spin 3/2*  $\rightarrow$  *spin 1/2 spin 0*  $\rightarrow$  *spin 1/2 spin 0 spin 0*

Consider the decay chain

$$\Omega^-(\frac{3}{2}^+) \rightarrow \Lambda(\frac{1}{2}^+) \text{K}^-(0^-) \rightarrow \text{p}(\frac{1}{2}^+) \pi^-(0^-) \text{K}^-(0^-)$$

The joint angular distribution depends on:

- 4 angles:  $\theta_\Lambda$ ,  $\phi_\Lambda$ ,  $\theta_p$ ,  $\phi_p$
- 4 asymmetry parameters:  $\alpha_\Omega$ ,  $\beta_\Omega$ ,  $\gamma_\Omega$ ,  $\alpha_\Lambda$
- 7 polarization parameters:  $r_{-1}^1$ ,  $r_0^2$ ,  $r_1^2$ ,  $r_2^2$ ,  $r_{-1}^3$ ,  $r_{-2}^3$ ,  $r_{-3}^3$

When the angles of the first decay are integrated out, one gets:

$$I(\theta_p, \phi_p) = \frac{1}{4\pi} (1 + \alpha_\Omega \alpha_\Lambda \cos \theta_p + \alpha_\Lambda \left( \frac{1}{2\sqrt{10}} r_{-1}^3 - \sqrt{\frac{3}{5}} r_{-1}^1 \right) (\beta_\Omega \cos \phi_p + \gamma_\Omega \sin \phi_p) \sin \theta_p)$$

- It is possible to extract  $\beta_\Omega$  and  $\gamma_\Omega$ !
- Using e.g. the Method of Moments, all the remaining 4  $r'_s$  can be determined

The moduli of the remaining 4 polarization parameters  $r_{-1}^1$ ,  $r_{-1}^3$ ,  $r_{-2}^3$ ,  $r_{-3}^3$  can be determined:

$$\begin{aligned}
 & \langle \sin \phi_\Lambda \cos \phi_p \rangle \\
 &= \int I(\theta_\Lambda, \phi_\Lambda, \theta_p, \phi_p) \times \sin \phi_\Lambda \cos \phi_p \, d\Omega_\Lambda \, d\Omega_p = \\
 &= -\frac{3\pi^2 \alpha_\Lambda \gamma_\Omega r_{-2}^3}{1024}
 \end{aligned}$$

$$\begin{aligned}
 & \langle (3 \cos \theta_\Lambda - 1) \sin \phi_p \rangle \\
 &= \int I(\theta_\Lambda, \phi_\Lambda, \theta_p, \phi_p) \times (3 \cos \theta_\Lambda - 1) \sin \phi_p \, d\Omega_\Lambda \, d\Omega_p = \\
 &= -\frac{\pi \alpha_\Lambda \gamma_\Omega r_{-1}^3}{4\sqrt{10}}
 \end{aligned}$$

...and...

$$\begin{aligned} & \langle \sin \phi_p \rangle \\ &= \int I(\theta_\Lambda, \phi_\Lambda, \theta_p, \phi_p) \times \sin \phi_p \, d\Omega_\Lambda \, d\Omega_p = \\ &= \frac{\pi \alpha_\Lambda \gamma_\Omega}{160} \left( -4\sqrt{15}r_{-1}^1 + \sqrt{10}r_{-1}^3 \right) \end{aligned}$$

$$\begin{aligned} & \langle \sin \phi_\Lambda \cos \phi_\Lambda \cos \phi_p \rangle \\ &= \int I(\theta_\Lambda, \phi_\Lambda, \theta_p, \phi_p) \times \sin \phi_\Lambda \cos \phi_\Lambda \cos \phi_p \, d\Omega_\Lambda \, d\Omega_p = \\ &= \frac{\pi \alpha_\Lambda \gamma_\Omega}{640} \left( 5\sqrt{6}r_{-3}^3 + 4\sqrt{15}r_{-1}^1 - \sqrt{10}r_{-1}^3 \right) \end{aligned}$$

# Summary & Outlook

Studying the  $\bar{p}p \rightarrow \bar{\Omega}^+\Omega^-$  reaction at PANDA, it will be possible to extract for the first time the following parameters:

- $\beta_\Omega, \bar{\beta}_\Omega$  relevant to the search for baryon CP violation in weak decays
- $\gamma_\Omega, \bar{\gamma}_\Omega$
- full spin density matrix  $\rho$  for the  $\Omega$  hyperon:
  - $r_0^2, r_1^2, r_2^2$  from angular distribution of  $\Omega \rightarrow \Lambda K$
  - $r_{-1}^1, r_{-1}^3, r_{-2}^3, r_{-3}^3$  from joint angular distribution of  $\Omega \rightarrow \Lambda K$  and  $\Lambda \rightarrow p\pi$

...Work in progress...

- Follow-up of E. Thomé's work and consistency check
- Simulation studies (W.I.Andersson – Uppsala group)
- Publication containing derivation of spin observables ( $\bar{p}p \rightarrow \bar{\Omega}\Omega$ ) and simulations

Thank you for your attention!

# CP Violation in Hyperon System

- No evidence for baryon CP violation so far
- $\bar{p}p \rightarrow \bar{Y}Y$  process suitable for CP measurements

CP violation parameters:

$$A = \frac{\Gamma\alpha + \bar{\Gamma}\bar{\alpha}}{\Gamma\alpha - \bar{\Gamma}\bar{\alpha}} \simeq \frac{\alpha + \bar{\alpha}}{\alpha - \bar{\alpha}}$$
$$B = \frac{\Gamma\beta + \bar{\Gamma}\bar{\beta}}{\Gamma\beta - \bar{\Gamma}\bar{\beta}} \simeq \frac{\beta + \bar{\beta}}{\beta - \bar{\beta}}$$

If CP is conserved, then:

$$\alpha = -\bar{\alpha} \rightarrow A \simeq 0$$

$$\beta = -\bar{\beta} \rightarrow B \simeq 0$$

where  $\Gamma$  is the partial decay width

- According to experiment  $A$  is consistent with 0 for  $\Omega$ ,  $\Lambda$ ,  $\Xi$
