

# QCD equation of state

at  $N_t=8$

Szabolcs Borsanyi  
Wuppertal

## outline

- I.  $N_f=0$
- II.  $N_f=3$
- III.  $N_f=2+1$
- IV. On the  $T_c$  controversy

based on mostly unpublished work by

Gergely Endrődi  
Zoltán Fodor  
Antal Jakovác  
Sándor Katz  
Kálmán Szabó  
(and myself)

# I. Quenched simulations

G. Boyd et al., Nucl. Phys. B469, 419 (1996) [hep-lat/9602007]; A. Papa, Nucl. Phys. B478, 335 (1996) [hep-lat/9605004]; B. Beinlich, F. Karsch, E. Laermann and A. Peikert, Eur. Phys. J. C6, 133 (1999) [hep-lat/9707023]; M. Okamoto et al. [CP-PACS Collaboration], Phys. Rev. D60, 094510 (1999) [hep-lat/9905005].

*Quenched is clean and cheap:*

so why don't lattice result come close to the SB limit?

where are high T results?

$g^6 \log(1/g) +$  fitted coeff for  $g^6$ :

Kajantie, Laine, Rummukainen, Schroder: **Phys.Rev.D67:105008,2003**

# Renormalization

Free energy (or the trace anomaly) has a  $T$ -independent quartic divergence.

Standard approach: remove  $p(T=0)$   *$T=0$  is too expensive*

Our approach:

We determine  $p(T)-p(T/2)$ :

$$p(T) = [p(T) - p(T/2)] + [p(T/2) - p(T/4)] + \dots$$

# Direct approach

In the standard approach the entire EoS can be calculated as an integral, but not individual pressure values. The direct approach calculates  $p(T)-p(T/2)$  at a single  $T$  temperature.

$$\bar{p} = \frac{1}{N_t N_s^3} \log Z(N_t) - \frac{1}{2N_t N_s^3} \log Z(2N_t) = \frac{1}{2N_t N_s^3} \log \left( \frac{Z(N_t)^2}{Z(2N_t)} \right)$$

$$\bar{p} \sim \log \left( \frac{Z(N_t)^2}{Z(2N_t)} \right) = \log \left( \frac{\bar{Z}(1)}{\bar{Z}(0)} \right) = \int_0^1 d\alpha \frac{d \log \bar{Z}(\alpha)}{d\alpha} = \int_0^1 d\alpha \langle S_{1b} - S_{2b} \rangle$$

[Endrodi *et al.* 0710.4197]

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\text{Diagram 1}}{\text{Diagram 2}}$$

$$\bar{Z}(\alpha) = \text{Diagram 3}$$

The diagrams are lattice configurations. Diagram 1 shows two separate square lattices of size  $N_t$  with boundary labels  $N_t-2$ ,  $N_t-1$ ,  $2$ ,  $1$ , and  $0$ . Diagram 2 shows a single larger square lattice of size  $2N_t$  with boundary labels  $2$ ,  $1$ ,  $0$ , and  $2N_t-1$ . Diagram 3 shows a square lattice with a vertical cut at position  $\alpha$ , with boundary labels  $(1-\alpha)$ ,  $\alpha$ ,  $\alpha$ , and  $(1-\alpha)$ .

# Direct approach

In the standard approach the entire EoS can be calculated as an integral, but not individual pressure values.

The direct approach calculates  $p(T)-p(T/2)$  at a single  $T$  temperature.

$$\bar{p} = \frac{1}{N_t N_s^3} \log Z(N_t) - \frac{1}{2N_t N_s^3} \log Z(2N_t) = \frac{1}{2N_t N_s^3} \log \left( \frac{Z(N_t)^2}{Z(2N_t)} \right)$$

$$\bar{p} \sim \log \left( \frac{Z(N_t)^2}{Z(2N_t)} \right) = \log \left( \frac{\bar{Z}(1)}{\bar{Z}(0)} \right) = \int_0^1 d\alpha \frac{d \log \bar{Z}(\alpha)}{d\alpha} = \int_0^1 d\alpha \langle S_{1b} - S_{2b} \rangle$$

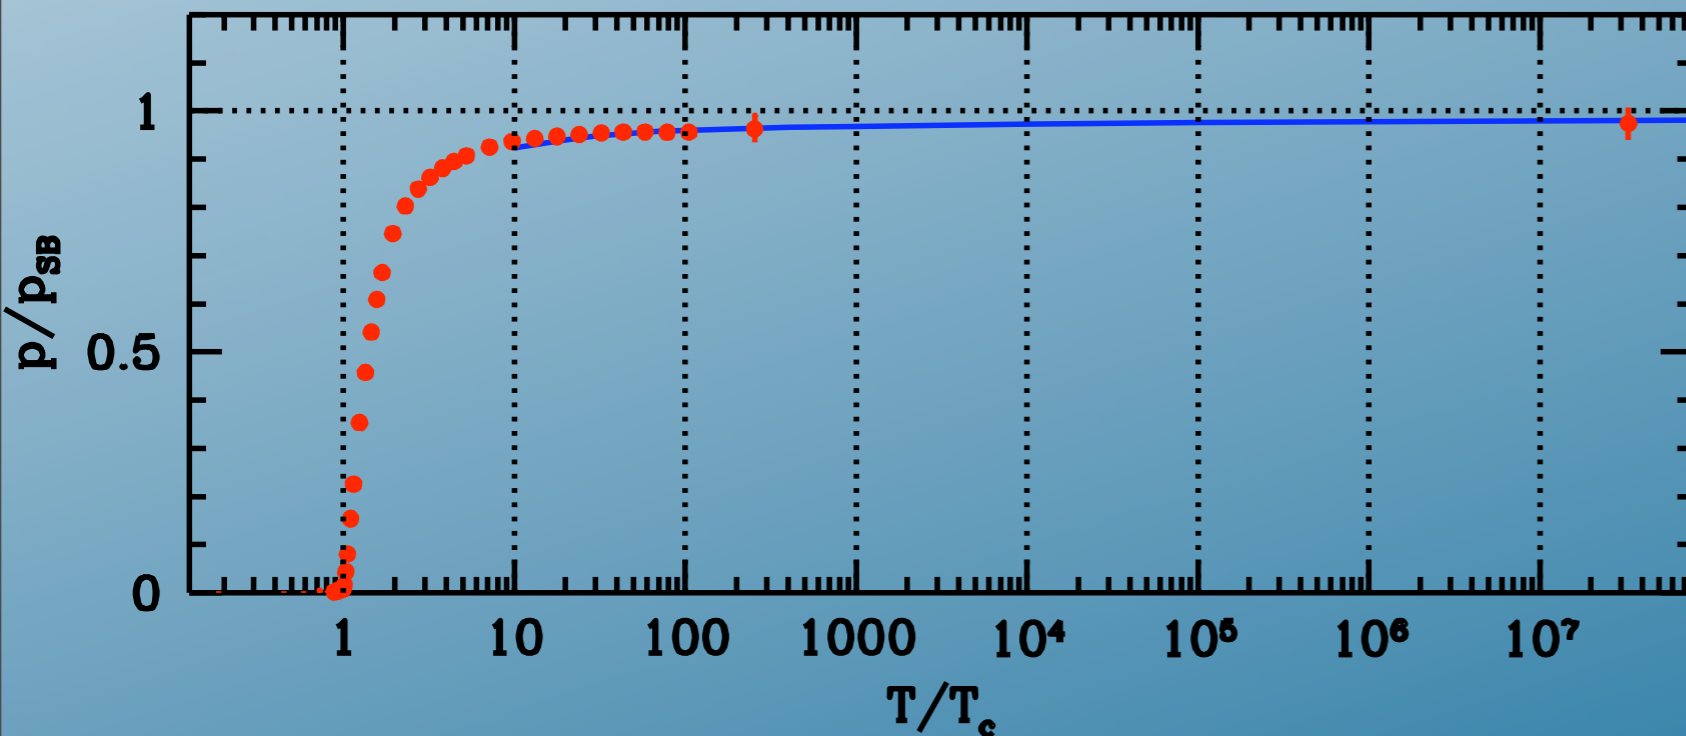

[Endrodi 0710.4197]

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\text{Diagram 1}}{\text{Diagram 2}}$$

Diagram 1: A square lattice with four corners marked by black squares. The top-left corner is labeled  $N_t-2$ , the top-right corner is labeled  $N_t-1$ , the bottom-left corner is labeled  $2$ , and the bottom-right corner is labeled  $0$ .

$$\bar{Z}(\alpha) = \text{Diagram 3}$$

Diagram 3: A square lattice with four corners marked by black squares. The top edge is labeled  $(1-\alpha)$ , the bottom edge is labeled  $(1-\alpha)$ , the left edge is labeled  $\alpha$ , and the right edge is labeled  $\alpha$ .

# Direct approach

In the standard approach the entire EoS can be calculated as an integral, but not individual pressure values. The direct approach calculates  $p(T)-p(T/2)$  at a single  $T$  temperature.

[Endrodi 0710.4197]

$$\bar{p} = \frac{1}{N_t N_s^3} \log Z(N_t) - \frac{1}{2N_t N_s^3} \log Z(2N_t) = \frac{1}{2N_t N_s^3} \log \left( \frac{Z(N_t)^2}{Z(2N_t)} \right)$$

$$\bar{p} \sim \log \left( \frac{Z(N_t)^2}{Z(2N_t)} \right) = \log \left( \frac{\bar{Z}(1)}{\bar{Z}(0)} \right) = \int_0^1 d\alpha \frac{d \log \bar{Z}(\alpha)}{d\alpha} = \int_0^1 d\alpha \langle S_{1b} - S_{2b} \rangle$$

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\text{Diagram 1}}{\text{Diagram 2}}$$

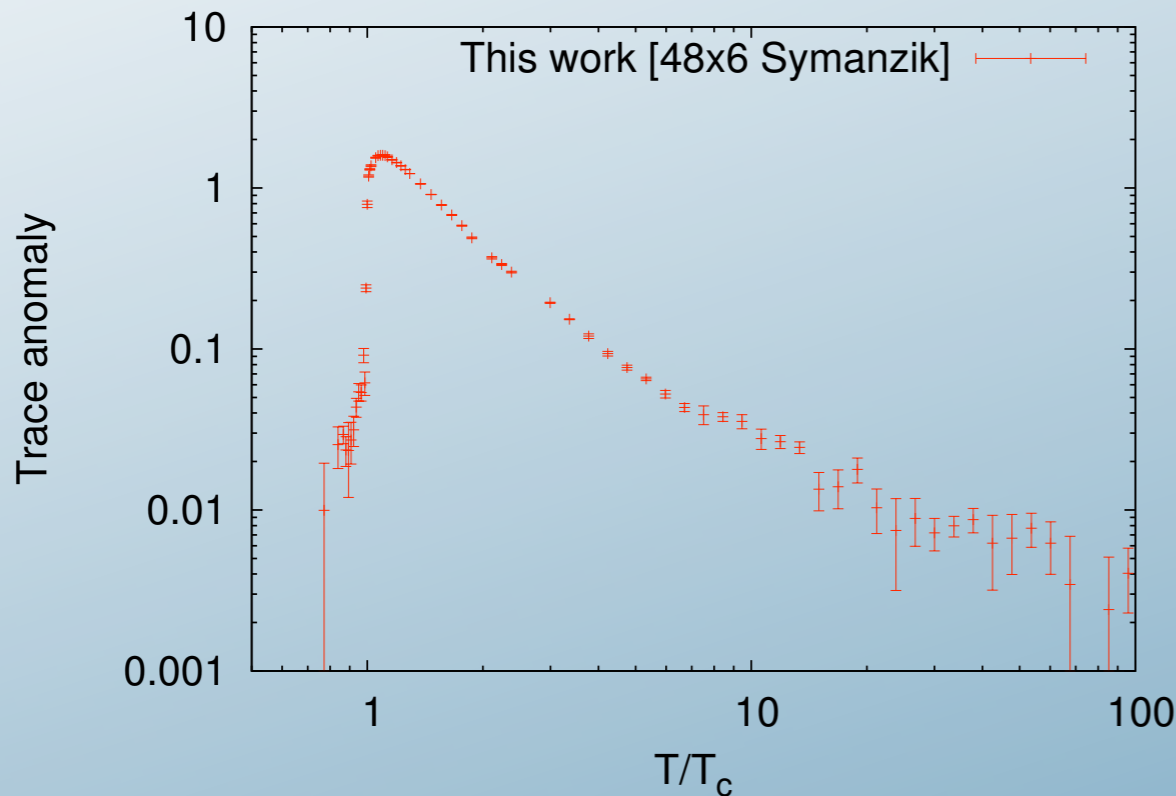

Diagram 1: A square lattice with  $N_t-2$  sites on the top edge,  $N_t-1$  sites on the right edge, and  $0$  sites on the bottom edge. The left edge has  $2$  sites on top and  $1$  site on bottom.

$$\bar{Z}(\alpha) = \text{Diagram 3}$$

Diagram 3: A square lattice with  $(1-\alpha)$  sites on the top edge,  $\alpha$  sites on the right edge, and  $(1-\alpha)$  sites on the bottom edge. The left edge has  $2$  sites on top and  $1$  site on bottom.

# The costs of high-T

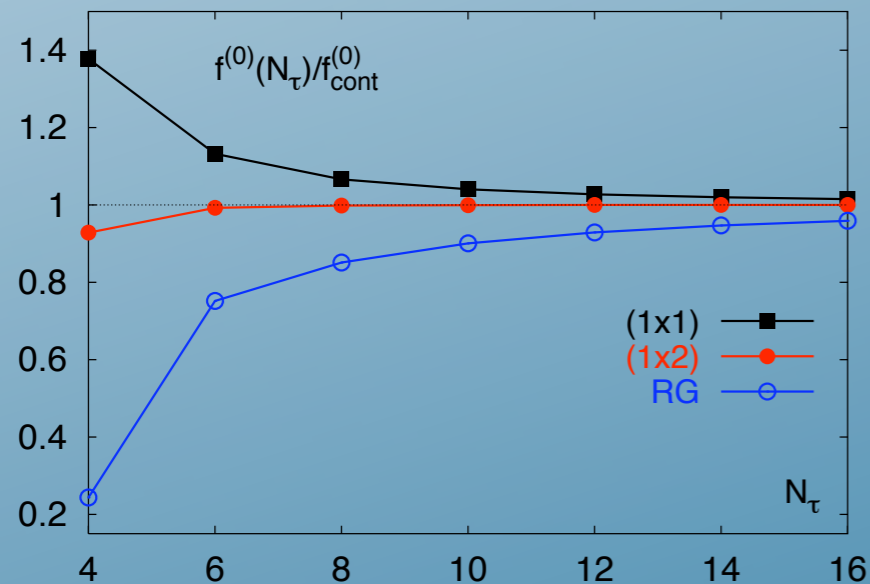

## Renormalization in practice:

Trace anomaly is obtained as the difference of two  $O(N_t^4)$  numbers

$$\frac{\Theta^{\mu\mu}(T)}{T^4} \equiv \frac{\epsilon - 3p}{T^4} = T \frac{\partial}{\partial T} (p/T^4)$$

Our choice: **Symanzik** action

Quenched code: 80-100 Gflop/s on a GPU

# Lattice vs perturbation theory

$g^6 \log(1/g)$  + fitted coeff for  $g^6$ :

# Lattice vs perturbation theory

$g^6 \log(1/g)$  + fitted coeff for  $g^6$ :

# II. $N_f=3$ QCD

Action: staggered fermions with fat links

$$S_g = \square + \square\square$$

$$S_f = \text{---} + \text{---} \quad \text{stout smearing } \rho=0.15$$

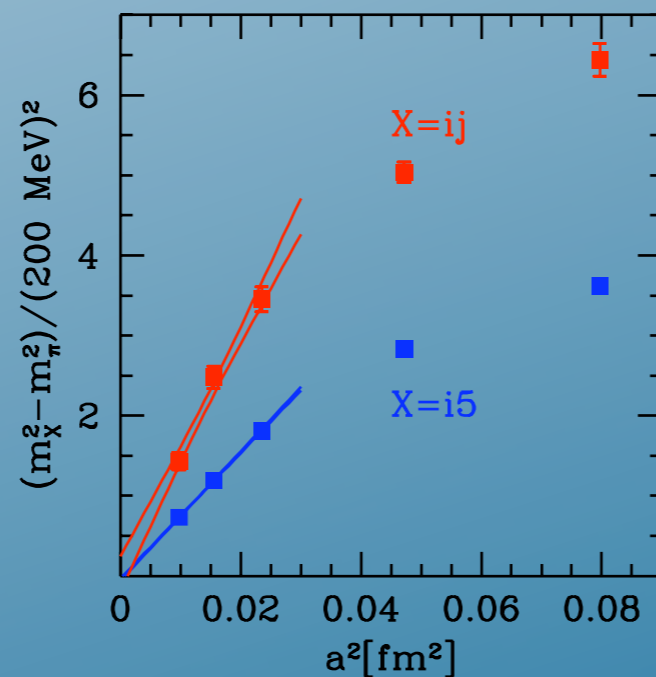

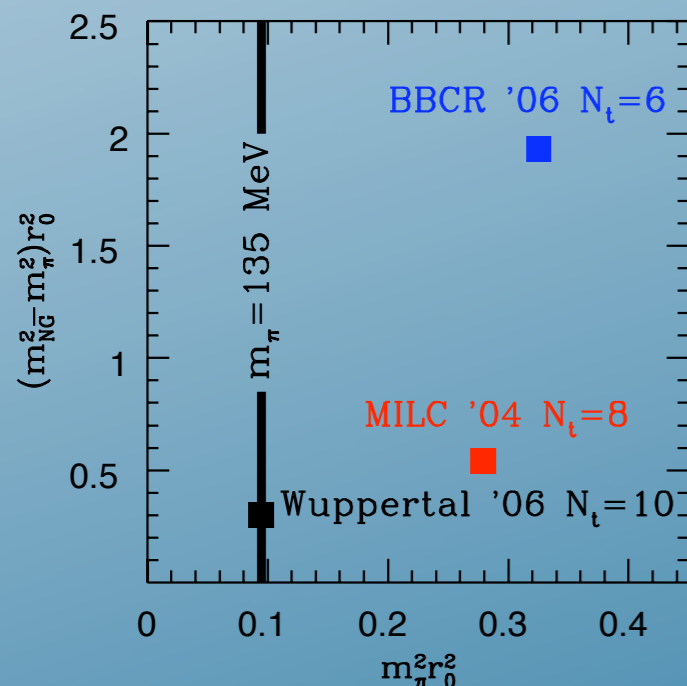

parameters  $N_{smr}=2$

(oversimplified)

Is staggered formulation appropriate? *Zero  $T$  physics matches experiment, UV physics matches perturbation theory*

Is the spectrum physical? *Pion splitting scales close to the continuum limit.*

*Stout smearing results in a balanced improved action: reduced taste symmetry breaking*

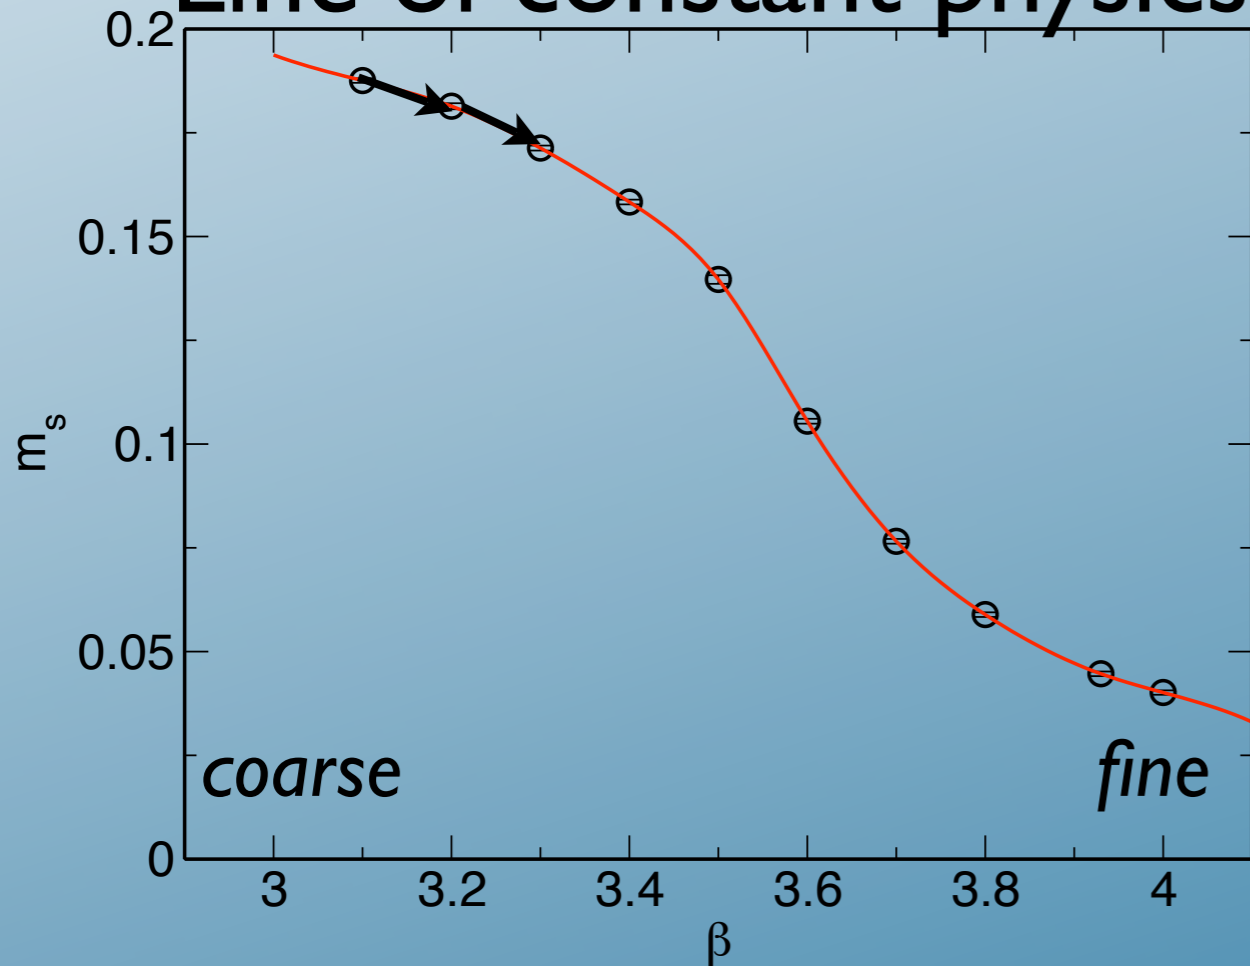

# Pressure is an integral in theory space

$$\frac{\Delta p}{T^4} = N_t^4 \int_{(\beta_0, m_{q0})}^{(\beta, m_q)} d(\beta, m_q) \left[ \frac{1}{N_t N_s^3} \left( \frac{\partial \log Z}{\partial \beta} \right) - \frac{1}{N_{t0} N_{s0}^3} \left( \frac{\partial \log Z_0}{\partial \beta} \right) \right]$$

with  $\langle \bar{\psi} \psi \rangle_q = \frac{T}{V} \frac{\partial \ln Z}{\partial m_q}$ ,  $q = l, s$ ,  $\langle S_g \rangle = -\frac{T}{V} \frac{\partial \ln Z}{\partial \beta}$

Line of constant physics:

beta  $\rightarrow$   $-\log(a)$   $\rightarrow$   $\log(T)$

Integration along the LCP

one integrates the trace anomaly.

gives  $p(T)/T^4 - p(T_0)/T_0^4$

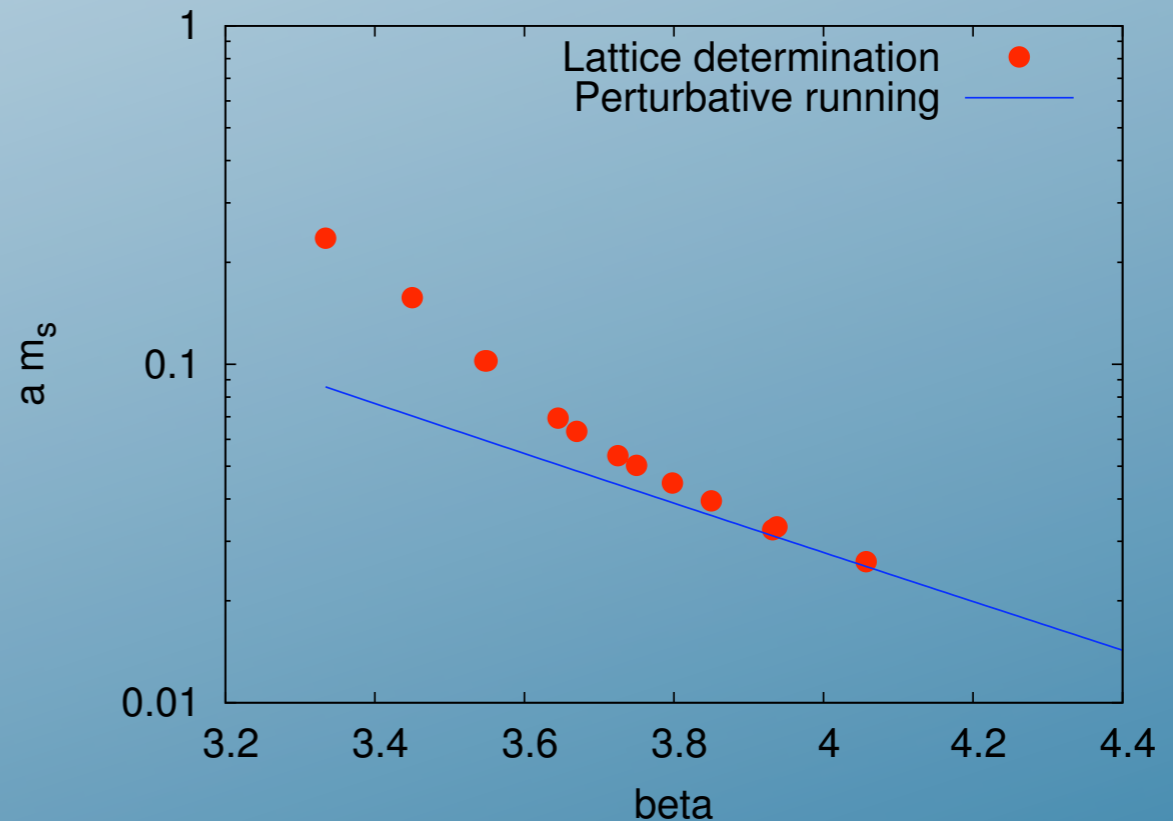

# Renormalization

Renorm. condition:  $m_K/f_K=495/155.5$   $m_\pi/f_K=135/155.5$   $N_f=2+1$   
 $m_{PS}/f_{PS} \approx 3.6$   $m_{PS} \approx 720 MeV$   $N_f=3$

## bare coupling

## bare mass

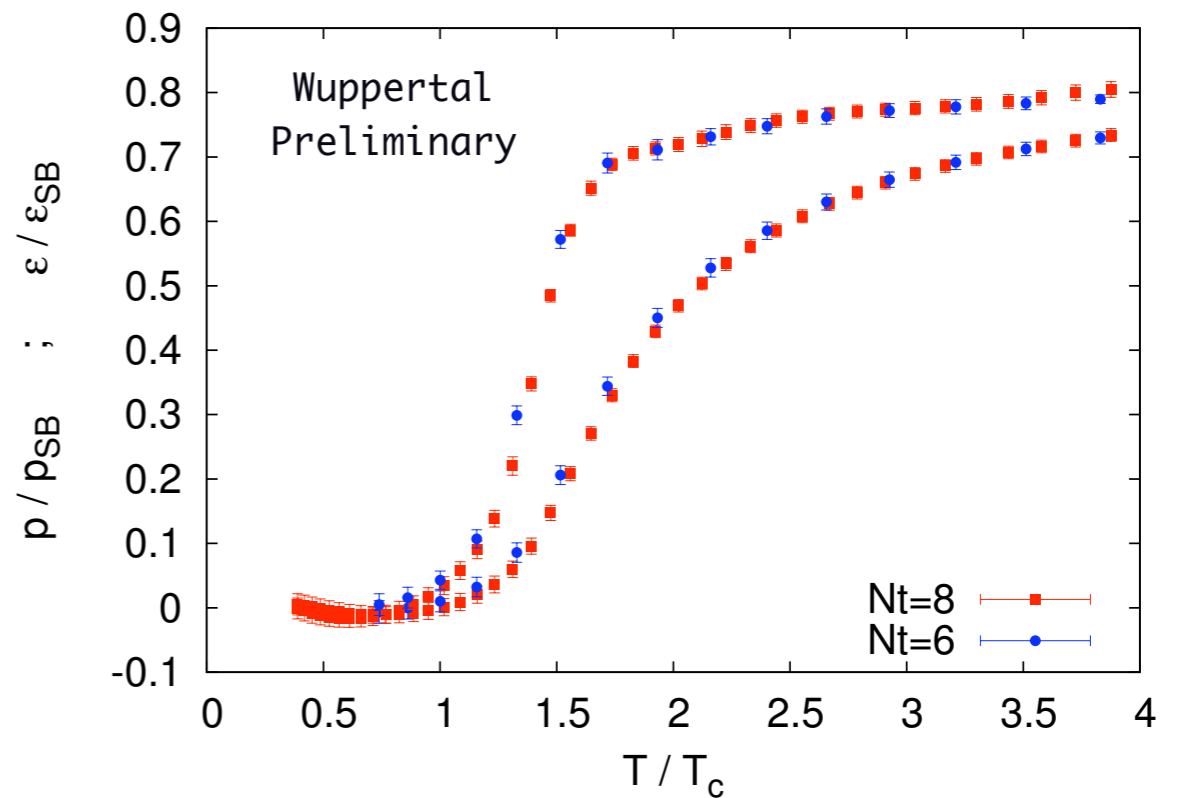

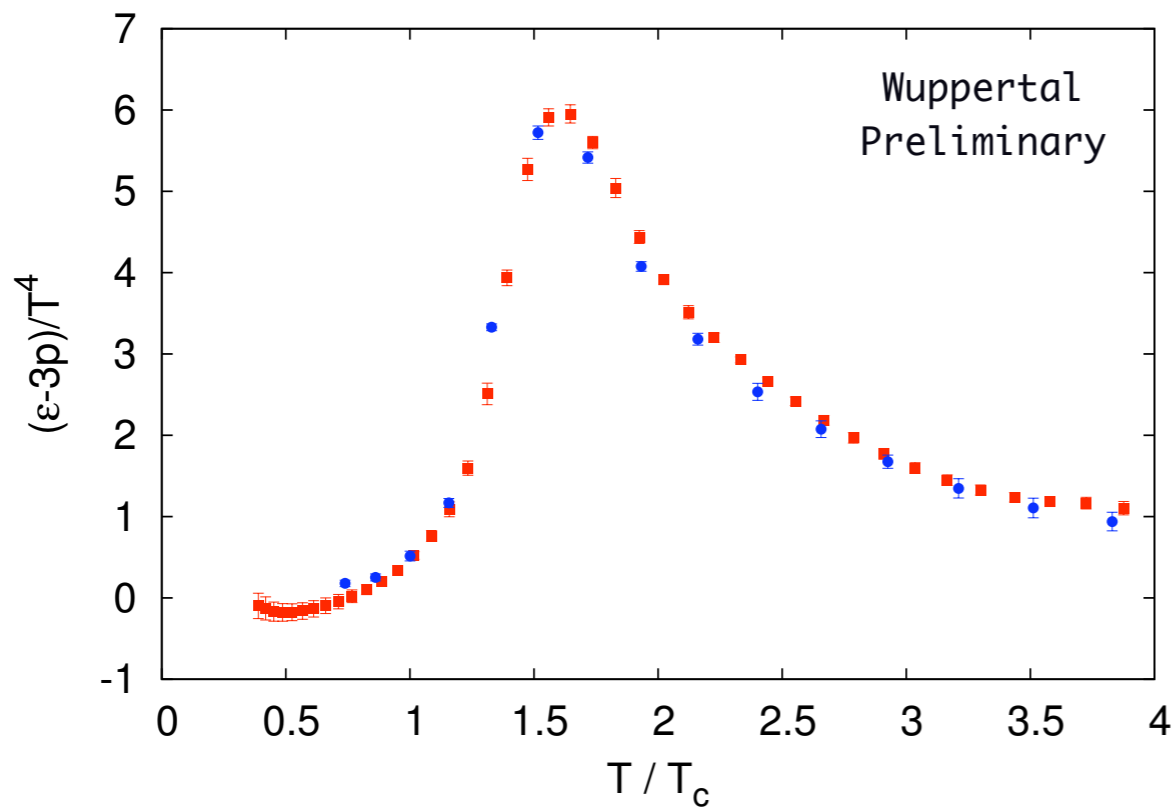

We reached perturbative running:  
we completed the renormalization for arbitrary high cut-off.  
This enables us to simulate an arbitrary high temperature.

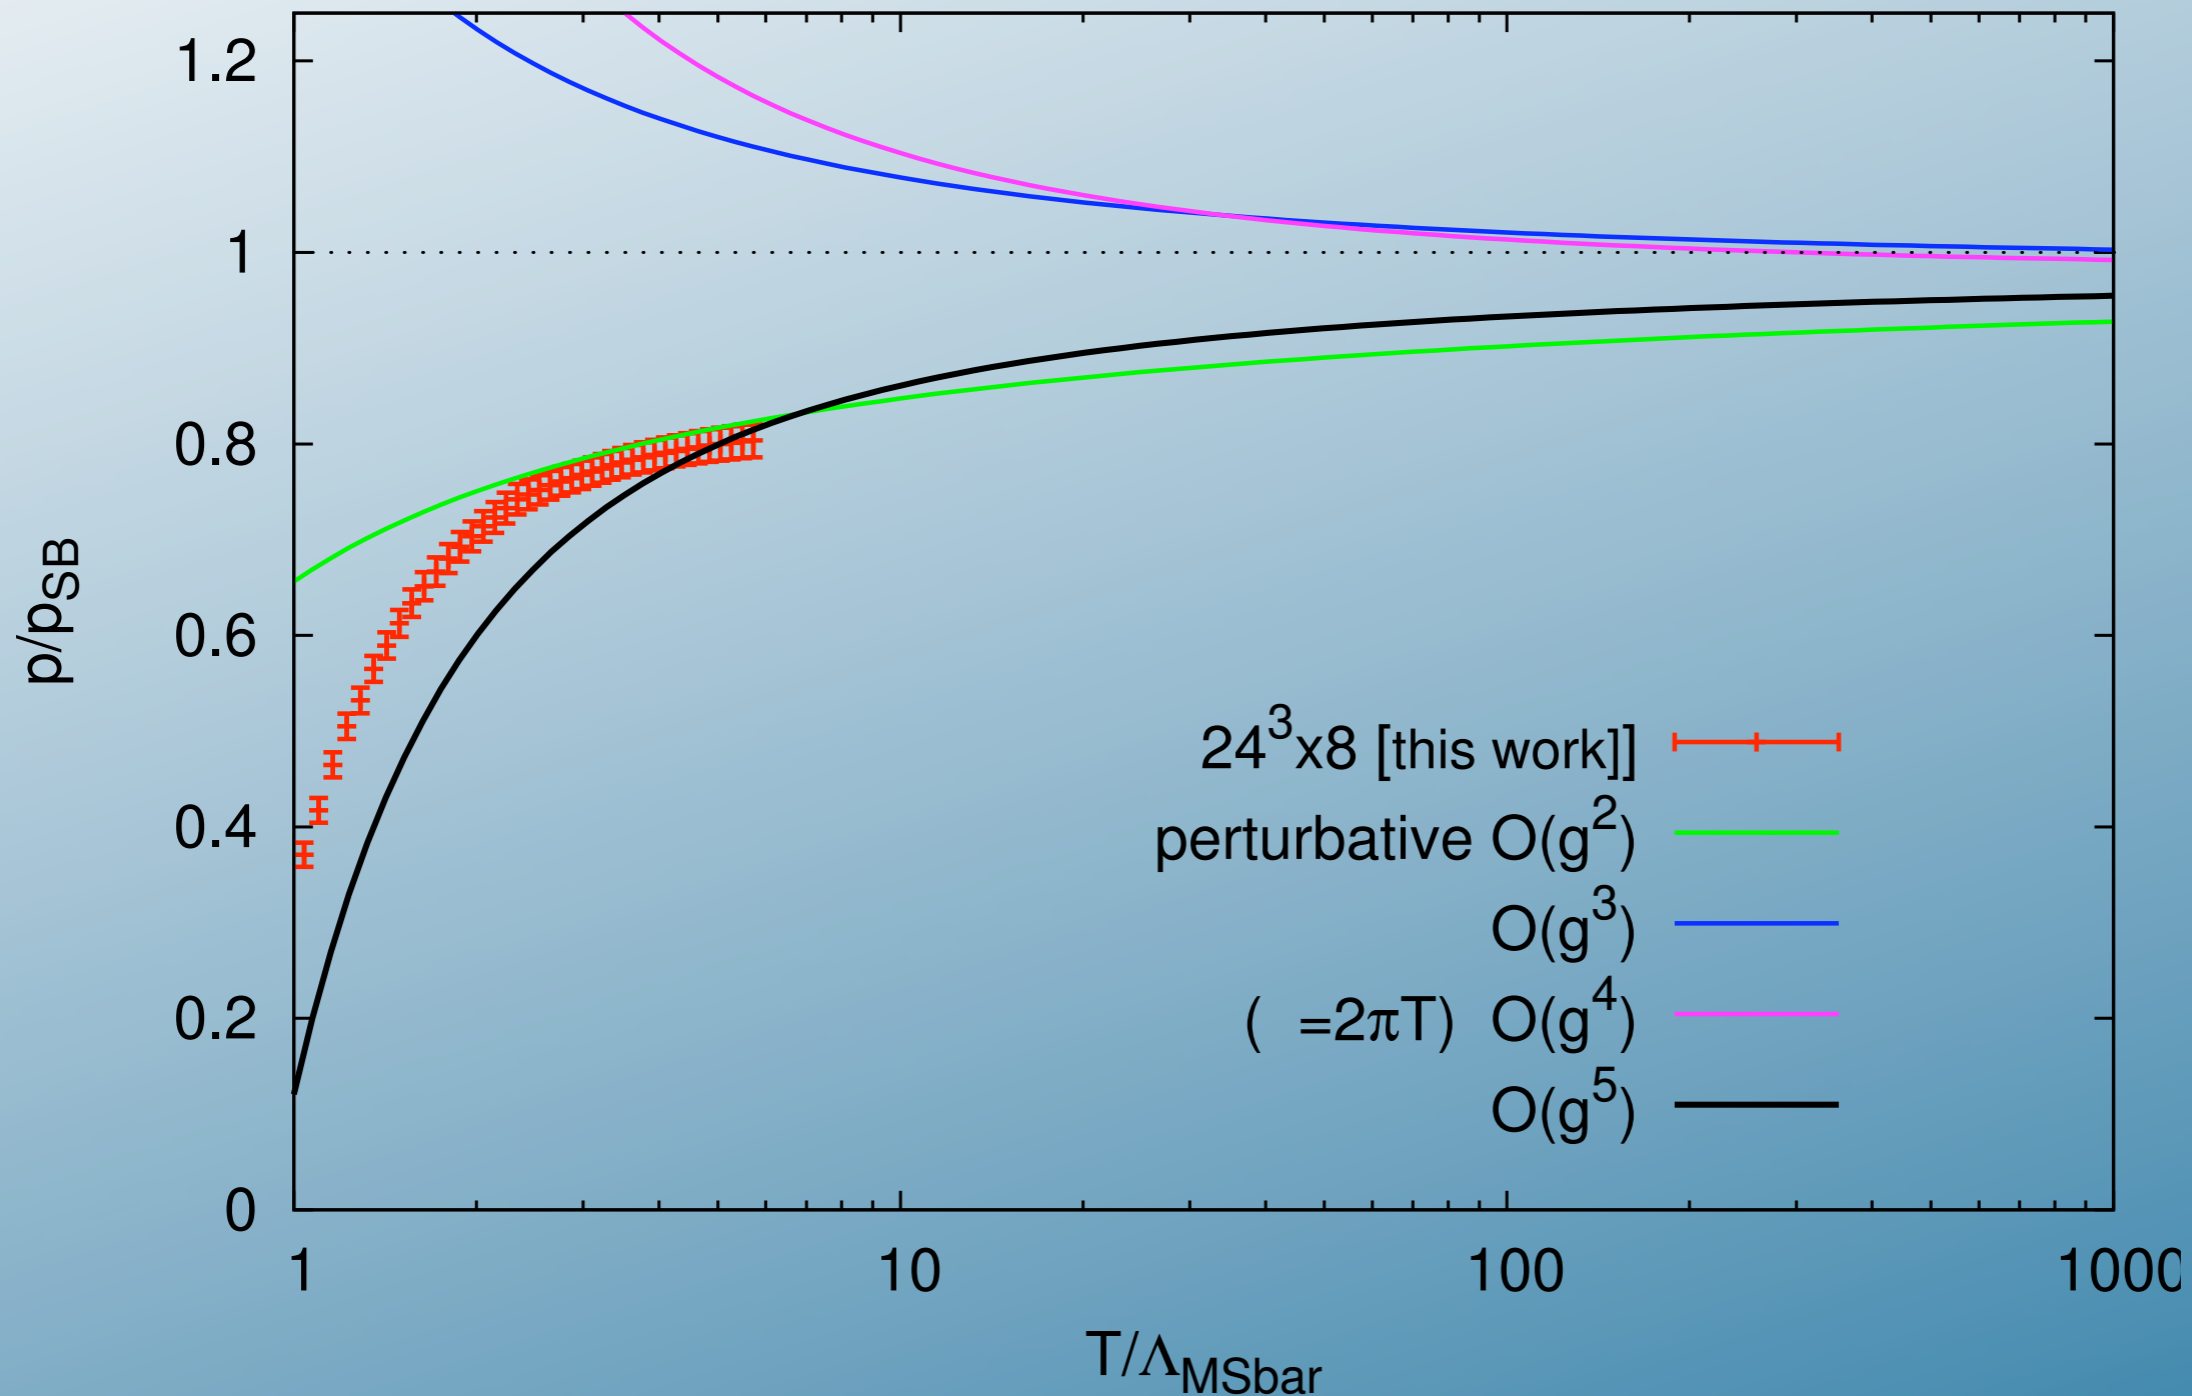

# Nf=3 equation of state

$$\Omega(T, V) = T \ln Z(T, V)$$

$$\frac{\Theta^{\mu\mu}(T)}{T^4} \equiv \frac{\epsilon - 3p}{T^4} = T \frac{\partial}{\partial T} (p/T^4) \quad p = \frac{1}{V} \Omega(T, V) \quad \epsilon = \frac{T^2}{V} \frac{\partial \Omega(T, V)/T}{\partial T}$$

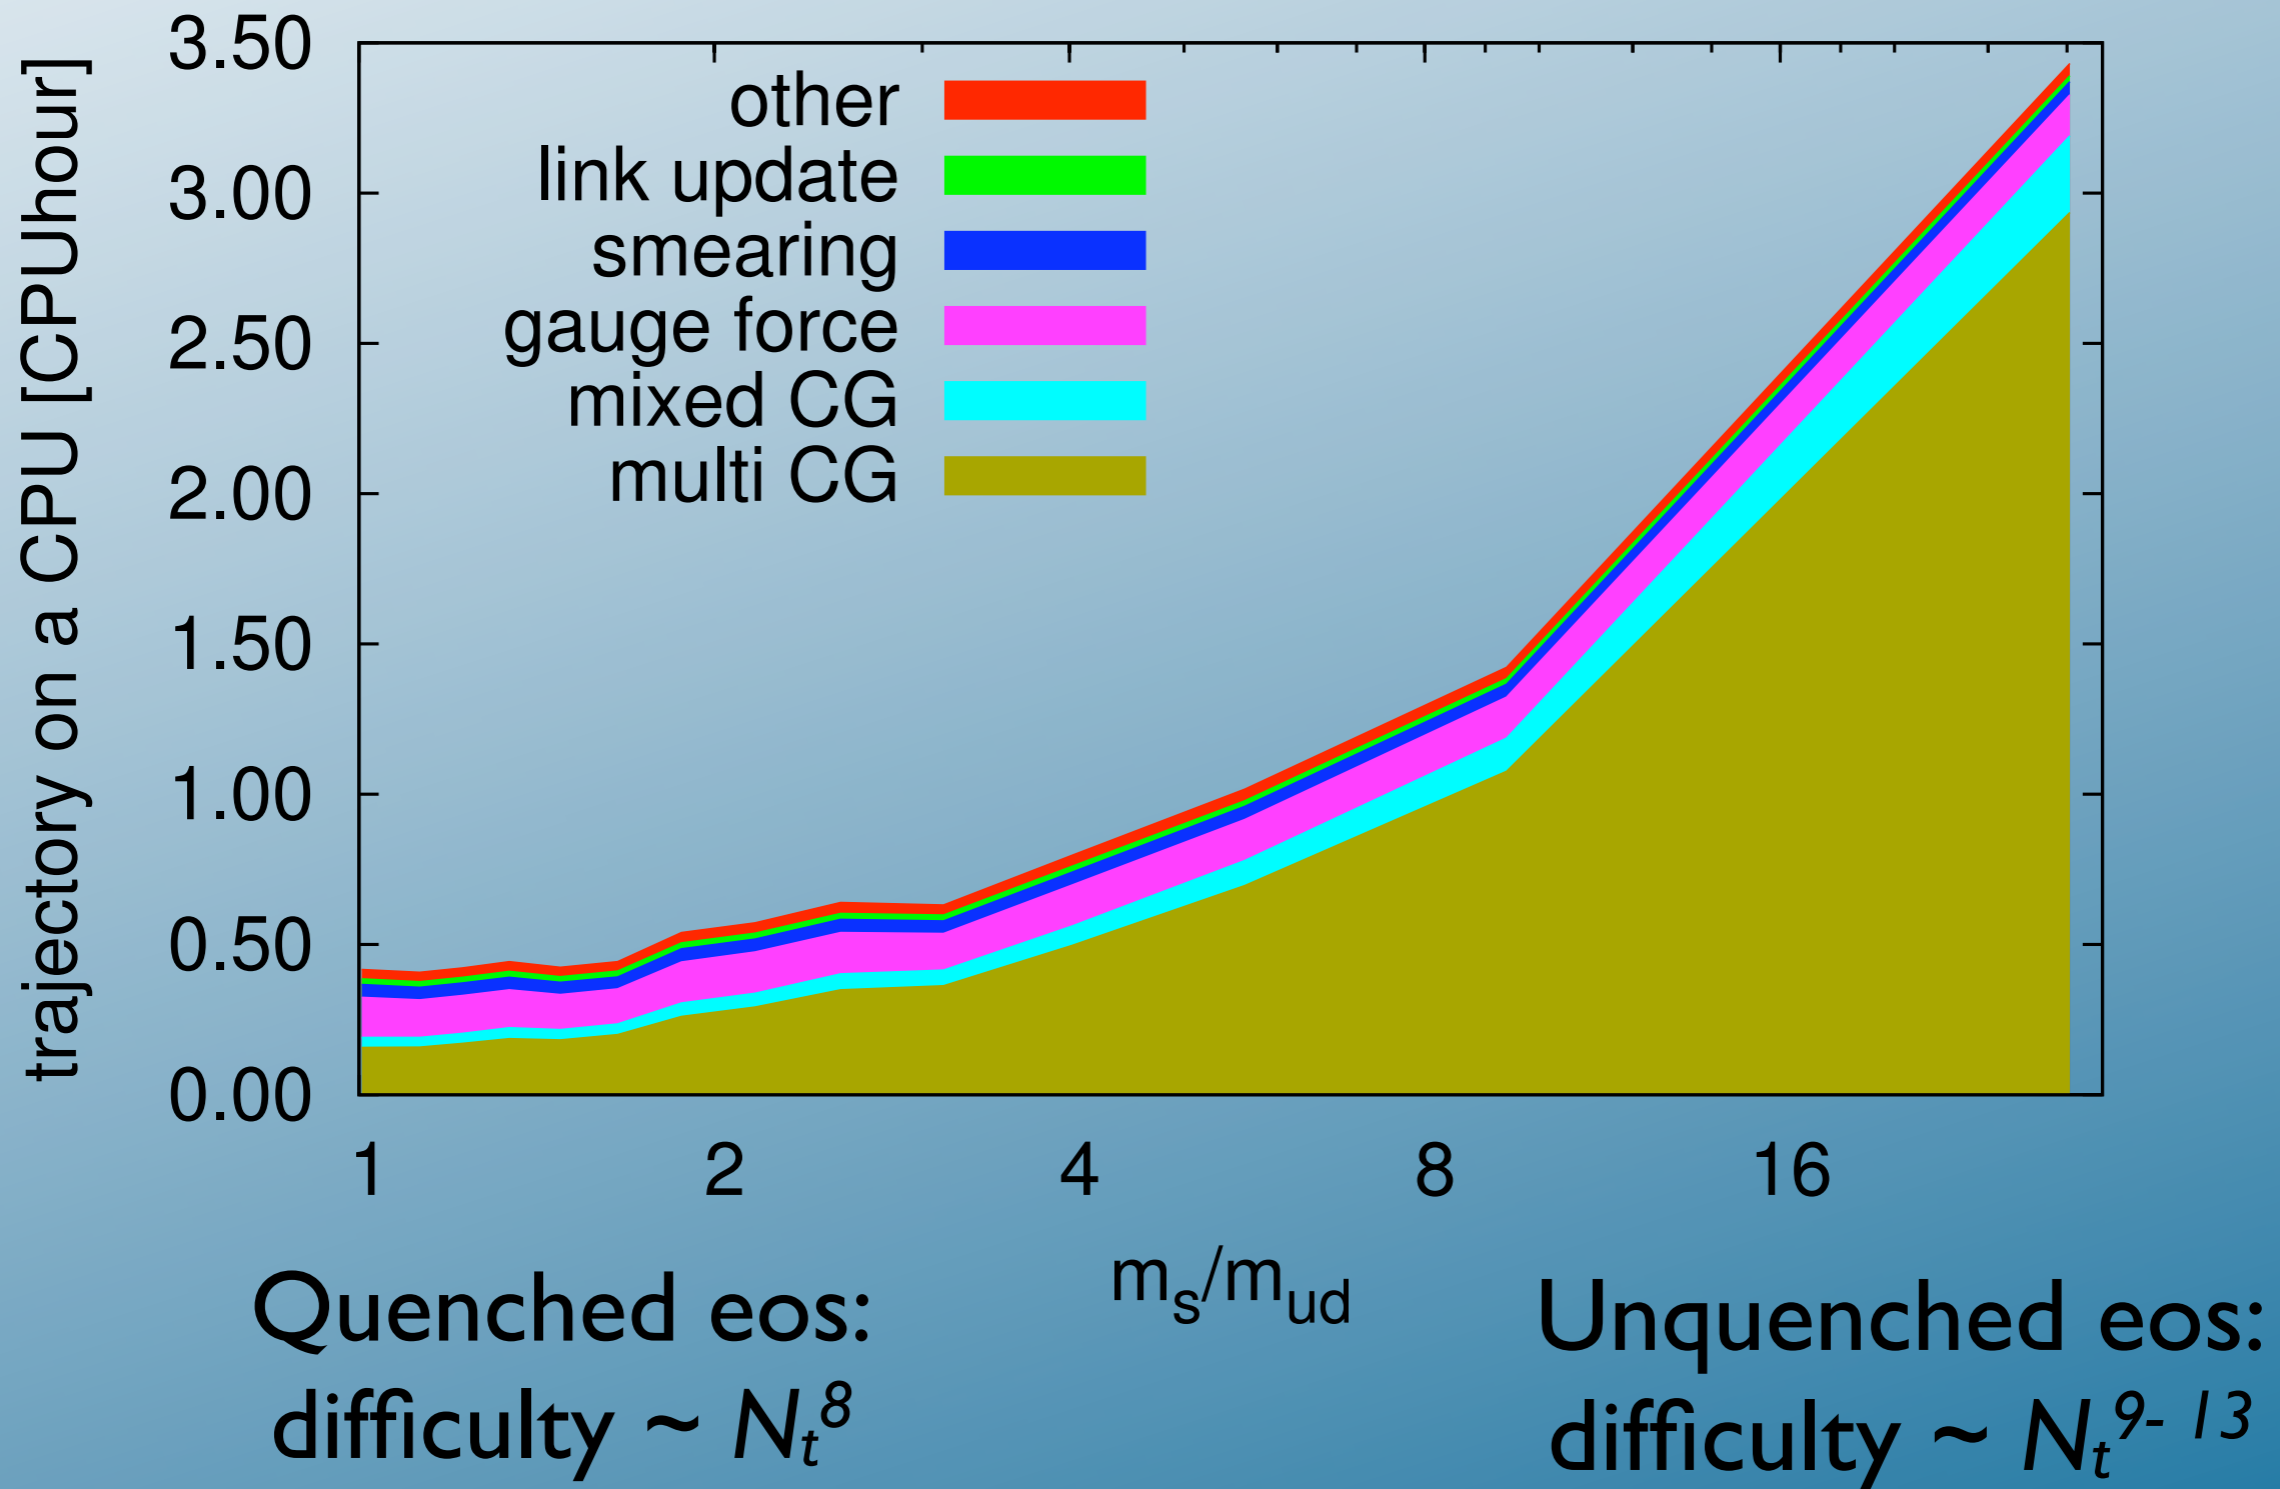

# Towards the perturbative limit

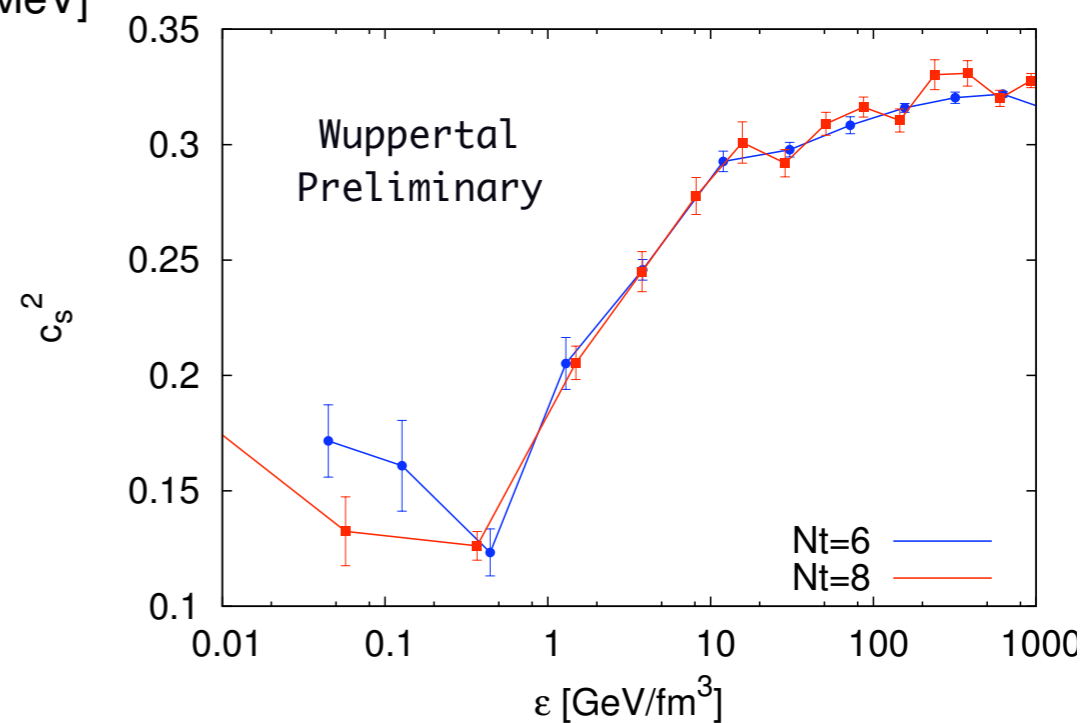

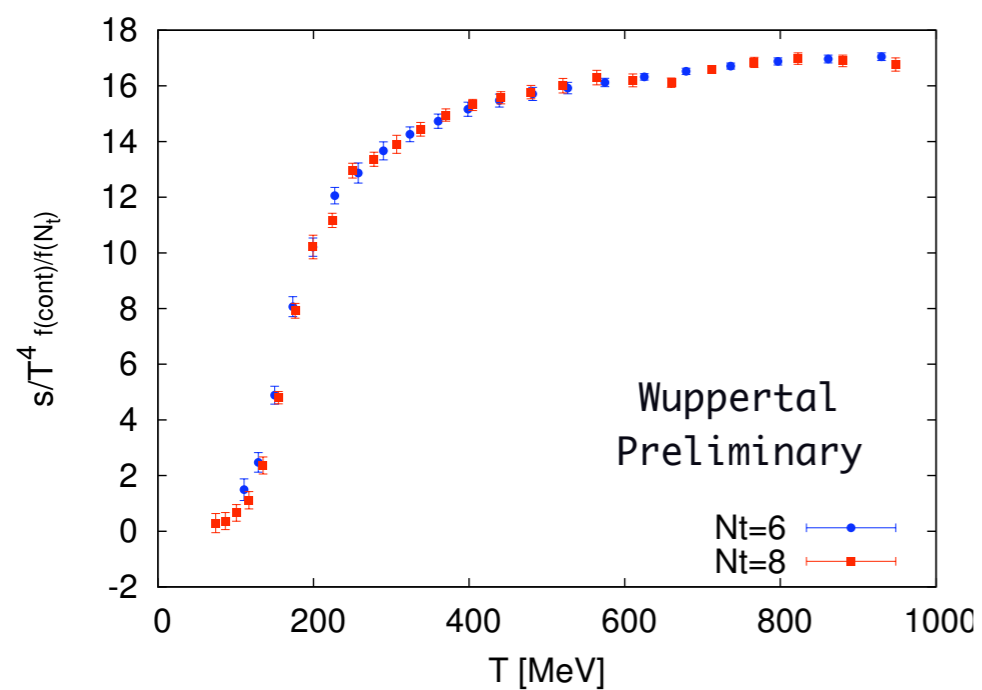

Note that the perturbative curves are very sensitive to:  
a)  $\Lambda_{QCD}$  b) renormalization. scale

# III. At physical quark mass

Cost of a trajectory ( $18^4$  lattice)

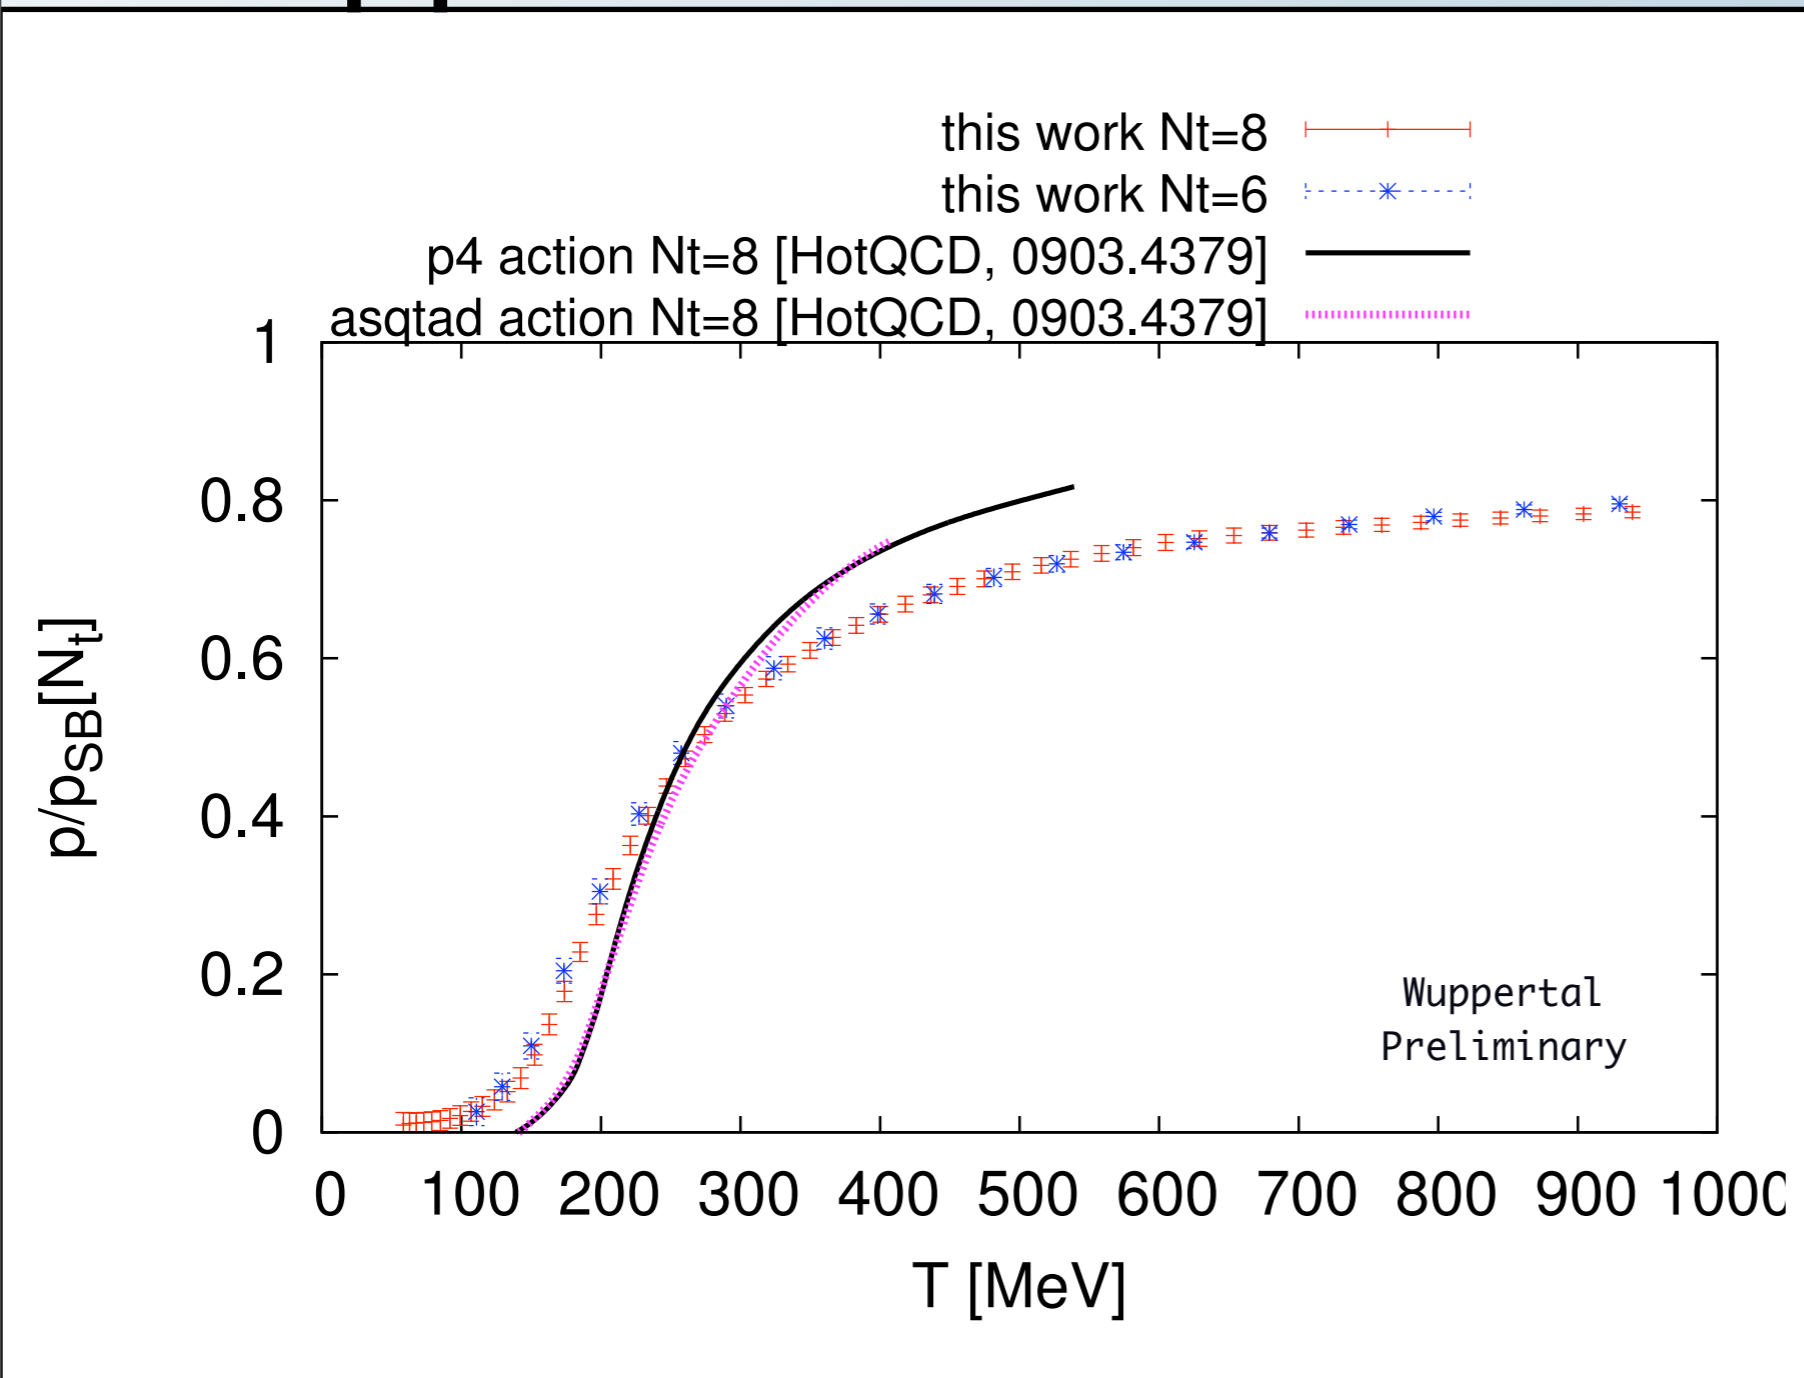

# The QCD equation of state

# Wuppertal vs HotQCD

Equation of state

- a)  $T_c$  discrepancy is manifest in EoS
- b) hotQCD EoS shoots up steeper

**p4**: optimized for infinite temperature

*(pert. improvement helps reaching the SB limit)*

**stout**: optimized for phase with broken chiral symmetry

*(smearing helps towards correct spectrum)*

# IV What sets the pion mass?

## Illustration:

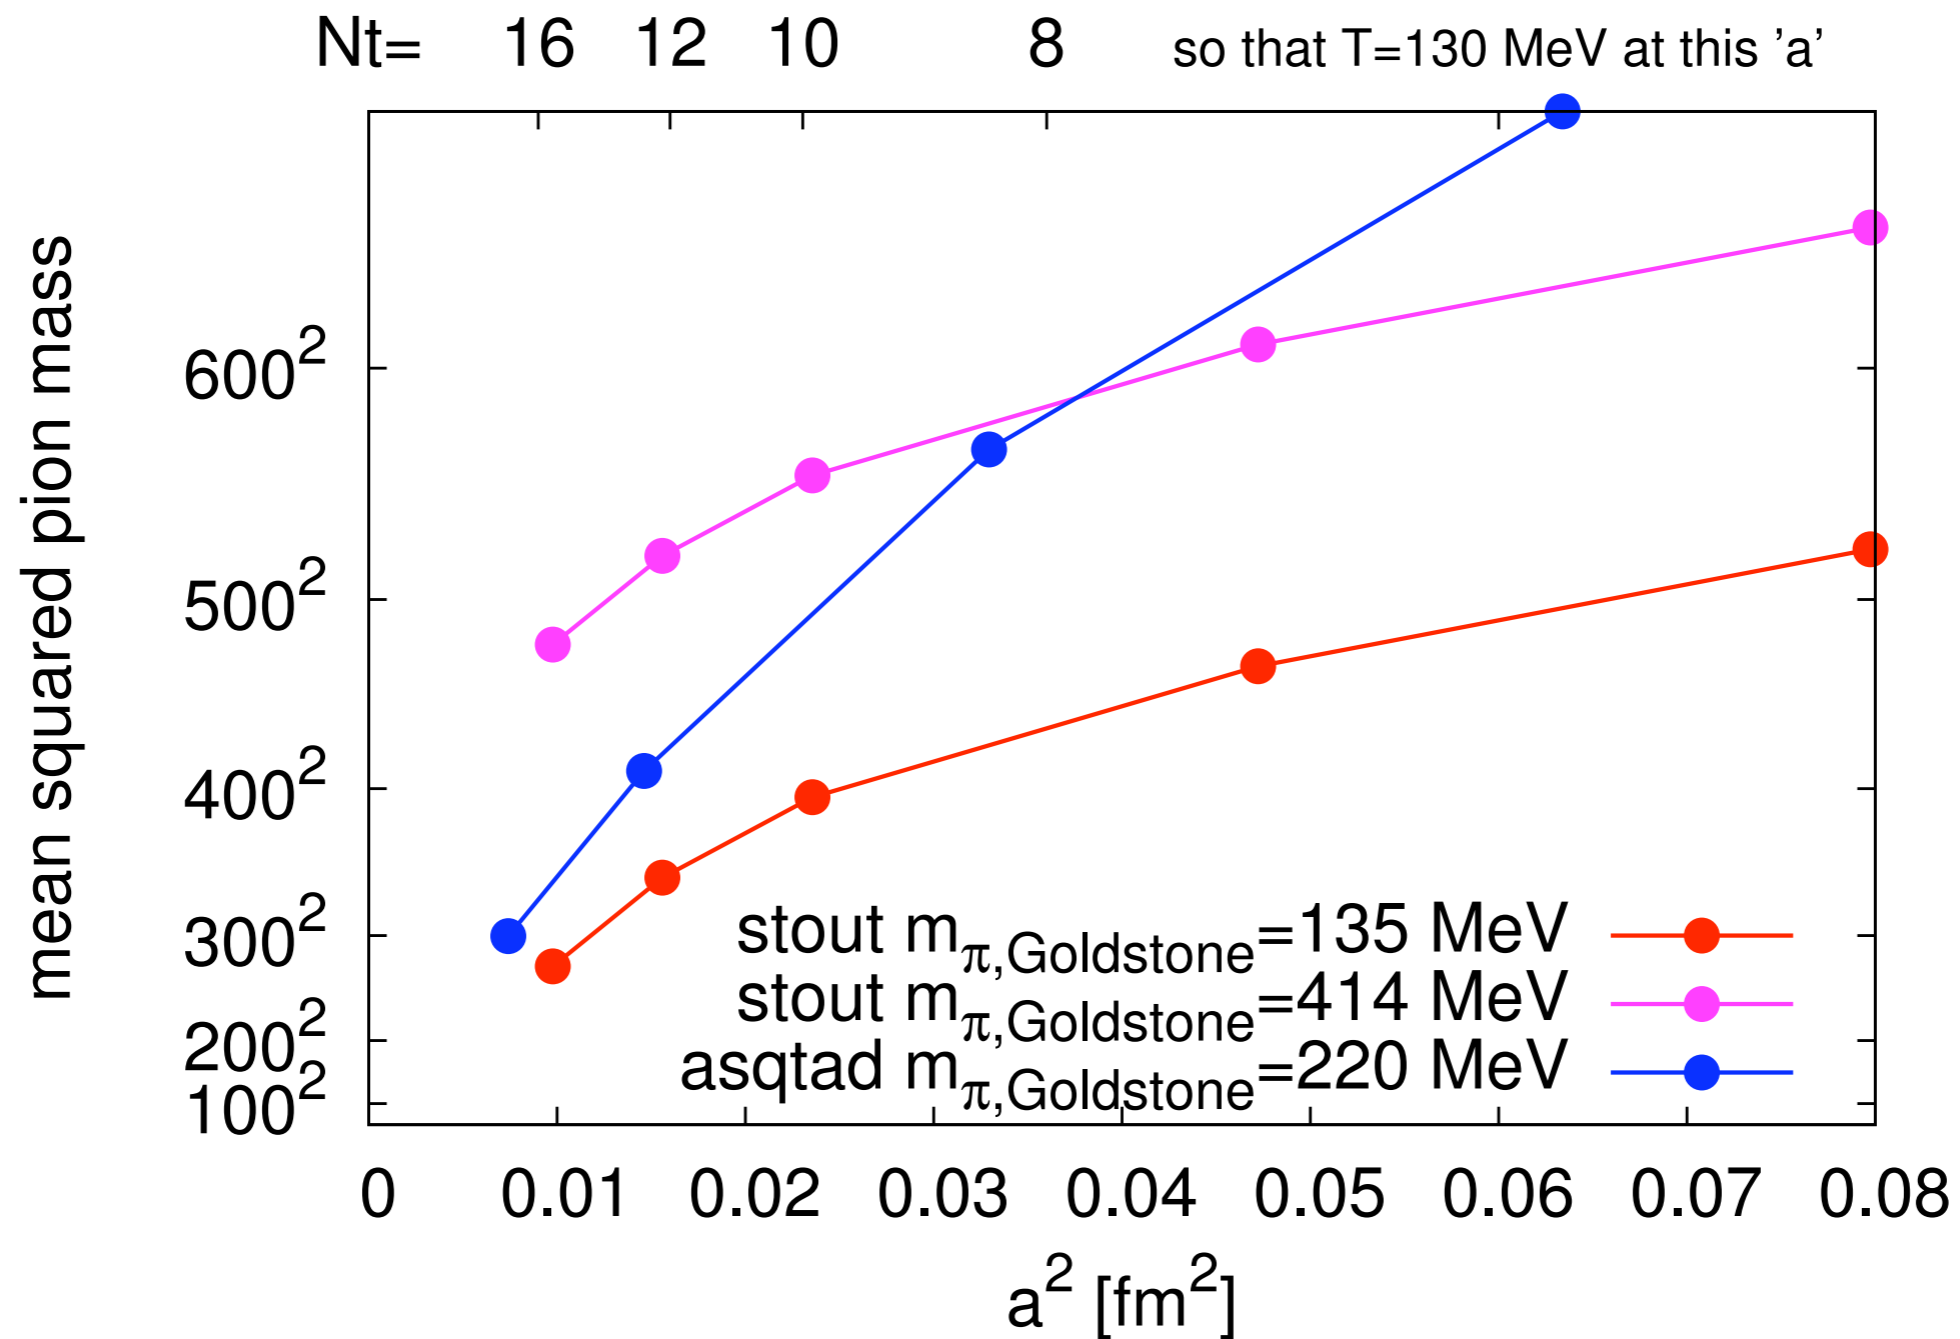

How to match Wuppertal and hotQCD results?

- Lattice artefacts for taste violation

*stout (Wuppertal) < asqtad (MILC) < p4 (Bielefeld)*

- We try to match asqtad's average pion mass by tuning our  $m_\pi$  (no perfect matching is possible)
- We repeat the  $T_c$  analysis with this heavier pion

# Matching the average pion mass

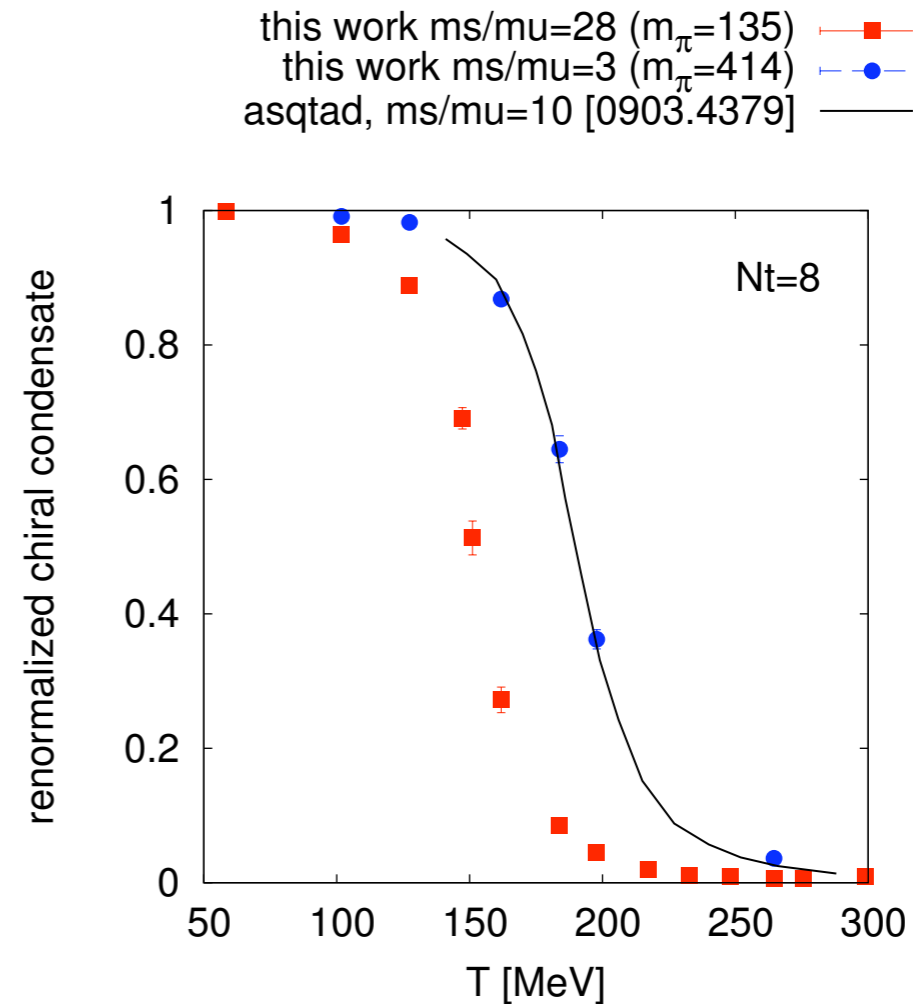

# Transition temperature vs pion mass

pressure

chiral condensate

We reproduce the hotQCD transition temperature with a heavier pion mass.

At that mass we see chiral and confinement transition at the same  $T_c$

# Message:

- We push the  $N_f=0$  and  $N_f=3$  equation of state towards the perturbative limit.
- Our  $N_f=2+1$  equation of state at  $N_t=4,6$  and  $8$  scales
- The discrepancy in  $T_c$  manifests in the equation of state  $p_4$  has a steeper and later (30 MeV) rise in the pressure.
- Our pion mass spectrum is significantly closer to physical than our competitor's;  
puts confidence in our simulations also below 200 MeV
- The transition pattern observed by the hotQCD collaboration might be reproduced with a “heavier pion”.
